## Contents

1 Introduction ..... 1
1.1 Short History \& State of the Art ..... 1
1.1.1 Three Concepts ..... 1
1.1.2 State of the Art ..... 2
1.2 Motivation ..... 4
1.3 Structure of the Lecture ..... 6
2 Polyprotic Acids ..... 7
2.1 What is an Acid? ..... 7
2.1.1 Proton Transfer ..... 7
2.1.2 Acidity Constants ..... 8
2.1.3 Mono-, Di-, and Triprotic Acids ..... 10
2.1.4 Strong Acids vs Weak Acids ..... 11
2.1.5 Weak Acids vs Dilute Acids ..... 12
2.2 Basic Set of Equations ..... 12
2.2.1 Special Case: Diprotic Acids $\left(\mathrm{H}_{2} \mathrm{~A}\right)$ ..... 12
2.2.2 General Case: Polyprotic Acids $\left(\mathrm{H}_{\mathrm{N}} \mathrm{A}\right)$ ..... 14
3 1-Component System: " $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ " ..... 17
3.1 The Subsystem "Pure Acid" ..... 17
3.1.1 Streamlined Notation ..... 17
3.1.2 Stepwise vs Cumulative Dissociation ..... 18
3.1.3 Generalized Henderson-Hasselbach Equations ..... 20
3.1.4 Closed-Form Expressions ..... 21
3.1.5 Inverse Task ..... 21
3.2 Equivalence Points ..... 22
3.2.1 Definition of Equivalence Points ..... 22
3.2.2 Assignment between $\mathrm{EP}_{\mathrm{n}}$ and $\mathrm{pH}_{\mathrm{n}}$. ..... 23
3.2.3 Summary \& Examples ..... 24
3.3 Ionization Fractions: Degree of Dissociation ..... 26
3.3.1 Definition of $a_{j}$ ..... 26
3.3.2 Bjerrum Plots \& Special Features of $a_{j}$ ..... 26
3.3.3 Two Types of $a_{j}$ : S-Shaped vs Bell-Shaped ..... 28
3.3.4 Two Types of Approximations ..... 29
3.4 Moments $Y_{L}$ : Weighted Sums over $a_{j}$ ..... 32
3.4.1 Definition of $Y_{L}$ ..... 32
3.4.2 Moments and EPs ..... 34
4 2-Component System: " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ " ..... 37
4.1 Basic Set of Equations ..... 37
4.2 Closed-Form Equations ..... 38
4.2.1 Forward and Inverse Task ..... 38
4.2.2 Examples ..... 39
5 Acid-Base System ..... 41
5.1 Introduction ..... 41
5.1.1 Definitions ..... 41
5.1.2 Special Case: Diprotic Acid ..... 42
5.2 Basic Set of Equations ..... 44
5.2.1 The 3-Component System ..... 44
5.2.2 Closed-Form Expressions ..... 45
5.2.3 Polynomials for $x=10^{-\mathrm{pH}}$ ..... 47
5.2.4 Lego-Set of Building Blocks ..... 48
5.3 Titration Curves ..... 48
5.4 Equivalence Points: General Approach ..... 50
5.4.1 Definitions ..... 50
5.4.2 $\mathrm{EP}_{\mathrm{n}}$ as Trajectories in $\mathrm{pH}-\mathrm{C}_{\mathrm{T}}$ Diagrams ..... 52
5.4.3 Summary: Systematics \& Classification ..... 53
6 Buffer Capacities ..... 57
6.1 ANC and BNC ..... 57
6.1.1 EPs as Reference Points of ANC and BNC ..... 57
6.1.2 Titration Example ..... 58
6.1.3 Alkalinity and Acidity ..... 59
6.1.4 pH as Reference Point of ANC and BNC ..... 61
6.2 Buffer Intensity ..... 61
6.2.1 From Buffer Capacity to Buffer Intensity ..... 61
6.2.2 Minima and Maxima (High- $C_{T}$ Limit) ..... 63
6.2.3 The General Case ..... 65
7 Application: Carbonate System ..... 69
7.1 Relationships between $\mathrm{pH}, C_{T}$, and Alkalinity ..... 69
7.2 Three Equivalence Points ..... 70
7.3 Acid-Base Titration with $\mathrm{H}_{2} \mathrm{CO}_{3}$ as Titrant ..... 72
7.4 Open vs Closed $\mathrm{CO}_{2}$ System ..... 73

## List of Symbols \& Abbreviations

| $a_{j}$ | ionization fractions, $a_{j}=[j] / C_{T}$ |  |
| :---: | :---: | :---: |
| Acy | acidity | $\mathrm{mol} / \mathrm{L}$ |
| Alk | total alkalinity (M-alkalinity) | $\mathrm{mol} / \mathrm{L}$ |
| ANC | acid-neutralizing capacity | $\mathrm{mol} / \mathrm{L}$ |
| BNC | base-neutralizing capacity | $\mathrm{mol} / \mathrm{L}$ |
| $C_{A}$ | concentration of strong monoprotic acid, $C_{A}=[\mathrm{HX}]_{\mathrm{T}}$ | $\mathrm{mol} / \mathrm{L}$ |
| $C_{B}$ | concentration of strong monoacidic base, $C_{B}=[\mathrm{BOH}]_{\mathrm{T}}$ | $\mathrm{mol} / \mathrm{L}$ |
| $C_{T}$ | total concentration of $N$-protic acid, $C_{T}=\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]_{\mathrm{T}}$ | $\mathrm{mol} / \mathrm{L}$ |
| $\mathrm{EP}_{j}$ | equivalence point (for integer $j$ ) | - |
| $\mathrm{EP}_{n}$ | equivalence point (for integer and half-integer $n$ ) |  |
| $G$ | molar GibBS energy | $\mathrm{J} / \mathrm{mol}$ |
| $I$ | ionic strength | $\mathrm{mol} / \mathrm{L}$ |
| $j$ | index denoting the aqueous species $j=0,1, \ldots, N$ |  |
| [j] | molar concentration of aqueous species $j$ : $[j]=\left[\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{A}^{j}\right]$ | $\mathrm{mol} / \mathrm{L}$ |
| \{j\} | activity of aqueous species $j$ : $\{j\}=\left\{\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{A}^{\mathrm{j}}\right\}$ | $\mathrm{mol} / \mathrm{L}$ |
| $\langle j\rangle$ | mean value of $j$ (real number between 0 and $N$ ) |  |
| $K_{a}$ | acidity constant (general abbreviation) | $\mathrm{mol} / \mathrm{L}$ |
| ${ }^{c} K_{a}$ | conditional acidity constant (non-thdyn quantity) | $\mathrm{mol} / \mathrm{L}$ |
| $K_{j}$ | acidity constant of dissociation step $j$ | $\mathrm{mol} / \mathrm{L}$ |
| $K_{\text {H }}$ | Henry constant | $\mathrm{mol} /(\mathrm{L} \cdot \mathrm{atm})$ |
| $k_{j}$ | cumulative acidity constant, $k_{j}=K_{1} K_{2} \cdots K_{j}$ | $(\mathrm{mol} / \mathrm{L})^{j}$ |
| $K_{w}$ | equilibrium constant of self-ionization of $\mathrm{H}_{2} \mathrm{O}$ | $(\mathrm{mol} / \mathrm{L})^{2}$ |
| $n$ | equivalent fraction, $n=\left(C_{B}-C_{A}\right) / C_{T}$ |  |
| $N$ | number of protons ( $\mathrm{H}^{+}$ions) of the $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ | - |
| $P$ | pressure | atm |
| pH | $=-\lg \{\mathrm{H} \equiv \mathrm{\}}=-\lg x$ | - |
| $\mathrm{pH}_{\mathrm{j}}$ | pH of equivalence point $\mathrm{EP}_{\mathrm{j}}: \mathrm{pH}_{\mathrm{j}}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right)$ | - |
| $\mathrm{pH}_{\mathrm{n}}$ | pH of equivalence point $\mathrm{EP}_{\mathrm{n}}$ | - |
| $\mathrm{pk}_{\mathrm{j}}$ | $=-\lg k_{j}$ | - |
| $\mathrm{pK}_{\mathrm{j}}$ | $=-\lg K_{j}$ |  |
| $R$ | universal gas constant | $\mathrm{J} /(\mathrm{mol} \mathrm{K})$ |
| $x$ | activity of $\mathrm{H}^{+}, x \equiv\left\{\mathrm{H}^{+}\right\}$ | $\mathrm{mol} / \mathrm{L}$ |
| $T$ | temperature | K or ${ }^{\circ} \mathrm{C}$ |
| $Y_{L}$ | $L^{\text {th }}$ moment constructed from $a_{j}: Y_{L}=\Sigma_{j} j^{L} a_{j}$ |  |
| $w(x)$ | pure water balance: $w \equiv\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right]=K_{w} / x-x$ | $\mathrm{mol} / \mathrm{L}$ |
| $Z$ | charge of highest protonated acid species | - |
| $z_{\text {av }}$ | average charge of acid: $z_{\mathrm{av}}=Z_{T} / C_{T}$ | - |
| $z_{j}$ | charge of species $j: z_{j}=Z-j$ |  |

$Z_{T} \quad$ total charge of acid
$\beta \quad$ (unitless) buffer intensity, $\beta=\mathrm{d} n / / \mathrm{d} \mathrm{pH}$
$\beta_{C} \quad$ buffer intensity, $\beta_{C}=\mathrm{d} C_{B} / \mathrm{dpH}=C_{T} \beta$
$\mathrm{mol} / \mathrm{L}$
$\beta_{j} \quad$ cumulative formation constants
$(\mathrm{mol} / \mathrm{L})^{-j}$
$\gamma_{j} \quad$ activity correction for species $j$

## Units and Conversions

L $\quad$ liter $\left(1 \mathrm{~L}=1 \mathrm{dm}^{3}=10^{-3} \mathrm{~m}^{3}\right)$
$\mathrm{M} \quad$ molarity ( $1 \mathrm{M}=1 \mathrm{~mol} / \mathrm{L}$ )
$\mathrm{mM} \quad 1 \mathrm{mM}=10^{-3} \mathrm{~mol} / \mathrm{L}$
$\lg x \quad$ decadic logarithm $\left(=\log _{10} x\right) \quad$ conversion: $\lg x=(\ln x) /(\ln 10)$
$\ln x \quad$ natural $\operatorname{logarithm}\left(=\log _{e} x\right) \quad$ conversion: $\ln x=(\ln 10) \cdot(\lg x)$
$\ln 10=2.303$

Abbreviations

| EDTA | ethylenediaminetetraacetic acid |
| :--- | :--- |
| EP | equivalence point |
| GEM | GIBBS energy minimization |
| LMA | law of mass action |
| NTA | nitrilotriacetic acid |
| PRL | proton reference level |
| thdyn | thermodynamics, thermodynamical |

## Some Definitions

Acid Species. The polyprotic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ has $N+1$ aqueous species, abbreviated by:

$$
\begin{equation*}
[j] \equiv\left[\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{~A}^{\mathrm{Z}-\mathrm{j}}\right] \quad \text { for } j=0,1,2, \ldots N \tag{1}
\end{equation*}
$$

Here the integer $j$ also labels the electric charge of species $j$ :

$$
z_{j}=Z-j \quad \text { with } \quad \begin{cases}Z=0 & \text { for common acids }  \tag{2}\\ Z \geq j & \text { for zwitterionic acids (e.g. amino acids) }\end{cases}
$$

Total Concentration. The sum of all species yields the total concentration of the acid:

$$
\begin{equation*}
C_{T} \equiv\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]_{\mathrm{T}}=\sum_{j=0}^{N}[j] \quad \text { (mass balance) } \tag{3}
\end{equation*}
$$

Ionization Fractions. Ionization fractions are ratios of the acid-species concentrations to the total amount of acid:

$$
\begin{equation*}
a_{j} \equiv \frac{[j]}{C_{T}} \quad \text { for } j=0,1,2, \ldots N \tag{4}
\end{equation*}
$$

Activities vs Concentrations. In chemical thermodynamics one has to distinguish between molar concentrations and activities (cf. Appendix A):

- concentrations denoted by square brackets [j]
- activities denoted by curly braces $\{j\}$
x and pH . The activity of $\mathrm{H}^{+}$will be abbreviated by $x$ :

$$
\begin{equation*}
x \equiv\left\{\mathrm{H}^{+}\right\}=10^{-\mathrm{pH}} \quad \Longleftrightarrow \quad \mathrm{pH}=-\lg x \tag{5}
\end{equation*}
$$

## Introduction

## Contents

1.1 Short History \& State of the Art ..... 1
1.2 Motivation ..... 4
1.3 Structure of the Lecture ..... 6

This lecture provides a detailed math description of the acid-base system, leading to analytical formulas that anyone can easily apply without effort to plot titration curves, BJERRUM plots and other diagrams. It covers and explains the first part of the review article [1].

### 1.1 Short History \& State of the Art

### 1.1.1 Three Concepts

The theory of acid-base reactions in water is not new; the subject has been studied for more than 100 years. Three main concepts were successively developed during this period:

- In 1884, Arrhenius provided the first modern, molecular-based definition: An acid is a substance that releases $\mathrm{H}^{+}$in water; a base is a substance that releases $\mathrm{OH}^{-}$. In this way, he predicted the dissociation into ions even before charged elementary particles were accepted and established (in the late 1890s). $\mathrm{H}^{+}$ions are just protons.
- In 1923, Brønsted and Lowry extended the concept with the idea that an acid-base reaction involves a proton transfer from a proton donor (the acid) to a proton acceptor (the base). The solvent no longer has to be water, as the new concept also applies to liquid ammonia, alcohol, benzene, and other non-aqueous solutions.
- About 15 years later, LEWIS went one step further and stretched the "protontransfer" concept of conventional acids and bases to the much broader concept of "electron-pair transfer": Acids are substances able to "accept" a lone pair of electrons from another molecule, designated as a base. The latter can also be used for ligand-metal ion coordination reactions and substitution reactions in organic chemistry.

The three concepts in Table 1.1 are shown as Venn diagram in Fig 1.1, where the Lewis concept encompasses both Brønsted-Lowry and Arrhenius theories. ${ }^{1}$

Table 1.1: Three acid-base concepts.

|  | acid | base |
| :--- | :--- | :--- |
| ARRHENIUS (1884) | contains $\mathrm{H}^{+}$ | contains $\mathrm{OH}^{-}$ |
| BRøNSTED-LOWRY (1923) | proton $\left(\mathrm{H}^{+}\right)$donor | proton $\left(\mathrm{H}^{+}\right)$acceptor |
| LEWIS (1938) | $\mathrm{e}^{-}$pair acceptor | $\mathrm{e}^{-}$pair donor |

The proton-transfer mechanism makes acid-base reactions very fast, so that chemical equilibrium is always established in a short time. This allows the application of a thermodynamic description (while slow reactions, such as redox processes, require more sophisticated kinetic approaches). The framework was established long ago in form of the Law of mass action (by Guildberg and Waage in 1864), where the equilibrium state is characterized by one single quantity - the equilibrium constant $K$. In modern-day chemistry this is derived from the GibBS energy (originally established in 1873).

### 1.1.2 State of the Art

## Acid-Base Equilibria

The topic of acid-base equilibria is covered in an extensive bibliography, usually focusing on mono- and diprotic acids, which is the entry point to understanding

[^0]chemical equilibrium reactions per se. The list of classical textbooks and monographs is long and stems from various subfields, such as hydrochemistry [2-4] as well as general and analytical chemistry [5-8]. This is accompanied with several modeling approaches, e.g., [9-11]. More advanced modeling approaches can be found for polyprotic acids.

## Polyprotic Acids

The mathematical description of polyprotic acids $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ (with $N \geq 3$ ) is a special topic that extends the traditional view on acid-base reactions. Algebraic equations are presented in [12-18]; their application to titration and buffer capacities can be found in [19-22] and in [23-28]. Many of the developments come from areas outside conventional hydrochemistry (e.g., organic and bio/med chemistry), which is the playground of proton-binding macromolecules such as nucleic acids and fulvic/humic acids. This also encourages a statistical description [29-32].

## Dissociation vs Association Reactions

There are two principal ways of math description:

- the approach in hydrochemistry (based on dissociation reactions with reference state $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ )
- the approach employed in organic and biochemistry (based on association reactions with reference state $\mathrm{A}^{-\mathrm{N}}$ )

The present lecture follows the first approach. [The interrelationship with the second approach is established in [1], Section 2.5.]

## Titration \& Buffer Capacities

Titration and buffer capacities are summarized in an excellent review article by Asuero and Michałowski [24]. This and other papers [22-26, 28] rely on association reactions (with reference state $\mathrm{A}^{-\mathrm{N}}$ ), so one has to be careful when comparing the formulas with the present approach.
[Most of these papers take the dilution during titration into account by explicitly using the volume of the titrant. This effect is ignored in this lecture to keep the formulas simple.]

## LMA vs GEM

For the general case of aquatic systems (as mixtures of any number of acids and bases plus solid and gaseous phases), there are two prototypes of numerical approaches:

- LMA: models that are based on the law of mass action (LMA) (e.g., PhreeqC [33, 34] and many others)
- GEM: models that are based on GibBS energy minimization [35, 36]

### 1.2 Motivation

Today, computers solve nonlinear systems numerically in the shortest time with high quality, which is a great help in dealing with complex real-world tasks (and we are grateful for that). However, by delegating everything to computers, we sometimes lose the overview of the underlying principles and functional relationships (digital data are too incomplete/imprecise to understand the deeper aspects of reality). Starting from the laws of mass action and mass/charge balance, a mathematical solution is provided in the form of simple and smooth analytical formulas for acid-base reactions. This is performed for the general case of $N$-protic acids, where $N$ can be any integer $(N \geq 1)$.
[In [1], the approach was applied to the broad class of zwitterionic acids $\mathrm{H}_{\mathrm{N}} \mathrm{A}^{+\mathrm{Z}}$ (amino acids, NTA, EDTA, etc.), which embeds all "ordinary acids" as a special sub-class characterized by $Z=0$.]

## Why do we need equations/formulas for $N>!2$ ?

Usually (and this is the first that comes to mind) $N$ is a small number: 1,2 or 3 for monoprotic, diprotic and triprotic acids. However, in reality, there are compounds with more protons, such as EDTA with $N=6$ (discussed in [1], Section 4.1.6) or other macromolecules in biochemistry and/or mixtures thereof. Moreover, when $N$ is treated as a variable integer, the equations teach us things that might otherwise be non-obvious (e.g., classification of equivalence points in §5.4).

## Is the approach mathematically strict?

The math derivation is strict. For this purpose, it is assumed that the activities (that enter the mass action laws) are replaced by molar concentrations, which is justified either for dilute systems or for non-dilute systems using conditional equilibrium constants (cf. seawater example in § 7.5). Deviations in the analytical model from numerical activity-based calculations are discussed in §7.6.

## What is the difference to standard approaches given in textbooks?

In textbooks [2-7], an algebraic solution of the acid-base problem is usually provided for diprotic acids $(N=2)$ in implicit form, namely as a polynomial of degree 4 in $x=10^{-\mathrm{pH}}$ (quartic equation!) - see, e.g., [2] (p. 107) or $\operatorname{Eq}(5.38)$ below. That is the common way to handle the acid-base problem. In the general case of $N$-protic acids, this procedure leads to polynomials of order $N+2$, where, for $N>4$, there is principally no algebraic solution (according to the Abel-Ruffini theorem). This dilemma will be avoided in the present approach. However, before we start, let us explain this in another way.

In titration, a titrant (strong base of amount $C_{B}$ ) is added to the analyte ( $N$ protic acid with amount $C_{T}$ ), resulting in a certain pH value. So, one is tempted to write the pH as a function of $C_{T}$ and $C_{B}$, that is:

$$
\begin{equation*}
\mathrm{pH}=\mathrm{pH}(\text { analyte }, \text { titrant })=\mathrm{pH}\left(C_{T}, C_{B}\right) \text { or } \mathrm{pH}=\mathrm{pH}\left(C_{T}, n\right) \tag{1.1}
\end{equation*}
$$

where $n=C_{B} / C_{T}$. However, as mentioned above, these relations cannot be expressed in the form of an explicit function; they only exist implicitly in the form of polynomials of degree $N+2$ (see (4.11) on page 39). So we put the whole thing "from head to toe" by providing a strict algebraic solution in the form of the

$$
\begin{equation*}
\text { explicit function: } n=n\left(\mathrm{pH}, C_{T}\right) \quad \text { or } \quad n=n\left(x, C_{T}\right) \tag{1.2}
\end{equation*}
$$

From the viewpoint of (1.2), the polynomials are then considered as the inverse task in §4.2.1.

## The lecture contains over 100 formulas. What is the central formula?

The central formula is the analytical formula for the explicit function (1.2):

$$
\begin{equation*}
n\left(x, C_{T}\right)=Y_{1}(x)+\frac{w(x)}{C_{T}} \tag{1.3}
\end{equation*}
$$

(symbols are explained in the text). This formula contains all information about the acid-base system in condensed form.

In this lecture, the function $n(x)$ appears under several names: equivalence fraction, titration function/curve, and normalized buffer capacity (because it measures the distance to $\mathrm{EP}_{0}$ ).

As sketched in Fig 1.2, depending on whether $n$ is a specific discrete number or a real function, different aspects appear: the equivalence points (as "special equilibrium states") or buffer capacities as "distances" between two equilibrium states.

Figure 1.2: Equivalent fraction $n$ as the central quantity from which all other quantities and formulas will be derived in this lecture.

## What does it mean to be a simple and smooth analytical formula?

"Simple" means that the analytical formulas are easy to handle in a Lego-like manner from plain constructs, as summarized in § 5.2.4. There is no need for programming or root-solving methods. All results and diagrams in this lecture were created with Excel, and anyone can easily reproduce them.
"Smooth" means that the analytical formula $n=n(x)$ or $n=n(\mathrm{pH})$ - as well as its building blocks - are infinitely derivable functions that offer calculus in the form of pH derivatives and integrals (a feature that is not possible for numerical solutions/data). The pH derivatives convert buffer capacities to buffer intensities; pH derivatives are also used to identify equivalence points (EPs) as local minima/maxima and/or inflection points.

### 1.3 Structure of the Lecture

Chapter 2 introduces the concept of polyprotic acids $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ for any number of protons $N$ (including all common mono-, di-, and triprotic acids characterized by $N=$ 1, 2, 3). Mathematically, this results in a system of $N+3$ nonlinear equations (cf. (2.32) to (2.37) on page 15). The goal of the next three Chapters is to bundle this set of $N+3$ equations into a single analytical formula. This is done in three subsequent steps (see also Fig 1.3):

- Chapter 3: 1-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ "
- Chapter 4: 2-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ "
- Chapter 5: 3-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}+$ base" (acid-base system)

In Chapter 3, we start with the 1 -component system i.e., the $N$-protic acid itself, which is fully determined by $N$ acidity constants $K_{1}$ to $K_{N}$. In Chapter $4, \mathrm{H}_{2} \mathrm{O}$ is included (by incorporating the self-ionization of water). In Chapter 5, the 2component system is extended to a 3 -component "acid-base system", which opens the door to the description of acid-base titrations. In all of these considerations, attention is drawn to the equivalence points (definition and classification), which can hardly be overestimated.

Figure 1.3:
Relationships between 1-, 2-, and 3 -component systems.

| 1-component system |  | 2-component system |  | 3-component system |
| :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \mathrm{H}_{\mathrm{N}} \mathrm{~A} \\ & \text { alone } \end{aligned}$ | $\stackrel{\mathrm{C}_{\mathrm{T}} \rightarrow \infty}{\longleftrightarrow}$ | $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ | $\stackrel{n=0}{\left(C_{B}=0\right)}$ | $\mathrm{H}_{\mathrm{N}} \mathrm{~A}+\mathrm{H}_{2} \mathrm{O}+$ <br> strong base |
| $\mathrm{K}_{\mathrm{j}}, \mathrm{a}_{\mathrm{j}}, \mathrm{Y}_{1}(\mathrm{x})$ | $\stackrel{n=0}{\stackrel{\left(C_{B}=0\right)}{ }}$ | $\mathrm{H}_{\mathrm{N}} \mathrm{~A}+$ <br> strong base | $\mathrm{C}_{\mathrm{T}} \rightarrow \infty$ | $n=Y_{1}(x)+\frac{w(x)}{C_{T}}$ |

[Note. Regarding the connection between the three subsystems in Fig 1.3, the numbers $1 / C_{T}$ and $C_{B} / C_{T}$ act as "coupling constants" of the acid to the water (autoprotolysis) and to the base.]

The concept of buffer capacities is introduced in Chapter 6. In Chapter 7, the derived concepts and formulas are applied to the carbonate system, such as alkalinity, open vs closed $\mathrm{CO}_{2}$-system, seawater, etc.

Chapter 8 briefly discusses some special/additional topics: (i) strong polyprotic acids, (ii) mixtures of acids, and (iii) the superposition of $N$ monoprotic acids (in order to generate an $N$-protic acid).

## Final Note

The presented mathematical framework is based on analytical formulas. In this way, it widens our understanding of the acid-base system. However, it will and can never replace numerical models like PhreeqC [33, 34], aqion [37] or other software, which are able to handle real-world problems (including activity corrections, an arbitrary number of species and phases, aqueous complex formation, etc.).

### 2.1 What is an Acid?

### 2.1.1 Proton Transfer

An acid HA is a proton donor; it releases $\mathrm{H}^{+}$ions (more precisely: $\mathrm{H}_{3} \mathrm{O}^{+}$) when dissolved in water:

$$
\begin{equation*}
\mathrm{HA}=\mathrm{H}^{+}+\mathrm{A}^{-} \tag{2.1}
\end{equation*}
$$

which is a shorthand for $\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})=\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq})$.
The definition of acids as proton donors is fully consistent with Arrhenius' conception that acids are substances that contain and release $\mathrm{H}^{+}$ions. In the case of bases, however, the concepts of Arrhenius and Brønsted-Lowry differ:
$\begin{array}{lll}\text { Arrhenius base } & \text { contains } \mathrm{OH}^{-} & \left.\text {(e.g. } \mathrm{NaOH}, \mathrm{KOH}, \mathrm{NH}_{4} \mathrm{OH}\right) \\ \text { Brønsted-Lowry base } & \mathrm{H}^{+} \text {acceptor } & \left(\text { e.g. } \mathrm{OH}^{-}, \mathrm{Cl}^{-}, \mathrm{NH}_{3}\right)\end{array}$
This allows all Arrhenius bases ${ }^{1}$ to be combined into a single $\mathrm{H}^{+}$acceptor equation:

$$
\begin{equation*}
\mathrm{OH}^{-}+\mathrm{H}^{+}=\mathrm{H}_{2} \mathrm{O} \tag{2.2}
\end{equation*}
$$

[^1]
## Conjugate Acids

Now something new comes into play (that the Arrienius concept does not have): conjugate acid-base pairs. Adding (2.2) to (2.1) yields:

$$
\begin{align*}
& \mathrm{HA}+\stackrel{\mathrm{OH}^{-}=\quad \mathrm{H}_{2} \mathrm{O}}{+} \quad \mathrm{A}^{-} \\
& \text {acid }+ \text { base }=\text { conjugate acid }+ \text { conjugate base }  \tag{2.3}\\
& \text { (of base } \mathrm{OH}^{-} \text {) (of acid HA) }
\end{align*}
$$

Note that $\mathrm{H}^{+}$ions do not occur in this overall reaction because they are transferred between conjugate acid-base pairs. $\mathrm{H}^{+}$ions occur only in "half reactions", such as in (2.1) or (2.2):

$$
\begin{gather*}
\text { acid }  \tag{2.4}\\
(\text { proton donor })
\end{gathered}=\mathrm{H}^{+}+\begin{gathered}
\text { conjugate base } \\
(\text { proton acceptor })
\end{gather*}
$$

$\mathrm{Eq}(2.4)$ is a general concept that applies to any polyprotic acid, namely for each individual dissociation step (as shown in (2.15) to (2.17) on page 10).

## Autoprotolysis

One special case of (2.3) is the self-dissociation of water:

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{O}+\mathrm{H}_{2} \mathrm{O}=\mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-} \tag{2.5}
\end{equation*}
$$

Here, the water acts simultaneously as an acid and a base. Such substances are termed ampholytes.

### 2.1.2 Acidity Constants

The equilibrium constant of reaction (2.1) is called acidity constant. There are two types of acidity constants:

| thermodynamic | $K_{a}=\frac{\left\{\mathrm{H}^{+}\right\}\left\{\mathrm{A}^{-}\right\}}{\{\mathrm{HA}\}}$ | (based on |
| :--- | :--- | :--- |
| acidity constant: | activities) |  |
| conditional acidity constant  <br> (of mixed type): ${ }^{c} K_{a}=\frac{\left\{\mathrm{H}^{+}\right\}\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}$ | (based on |  |
| concentrations) |  |  |

The last equation represents a mixed-type constant since we use the activity for $\mathrm{H}^{+}$but the concentrations for all other components.

The two equations are special types of the law of mass action. The value of $K_{a}$ signifies the strength of the acid (strong acids: $K_{a}$ large; weak acids: $K_{a}$ small).

## Activities

Activities are "effective concentrations" which can be calculated by semi-empirical activity corrections $\gamma_{j}$ for each species $j$ (cf. Appendix A):

$$
\begin{equation*}
\text { activity (effective concentration): } \quad\{j\}=\gamma_{j}[j] \tag{2.8}
\end{equation*}
$$

The activity corrections increase with the ionic strength $I$ of the solution. In ideal or near-ideal solutions (i.e. diluted systems) we have $I \simeq 0$ and $\gamma_{j} \simeq 1$, so that activities and concentrations are (almost) the same.

Note. The derivations in this lecture rely on concentrations (except for $\mathrm{H}^{+}$, where we use the activity). Thus, the obtained results are valid either in dilute systems or by using the conditional acidity constant ${ }^{c} K_{a}$. We consider it as an assumption that applies to the whole text (and skip the small-letter superscript $c$ on ${ }^{c} K_{a}$ ).

## $\lg \mathrm{K}$ Value

In practice, it is convenient to use the decadic logarithm of (2.7):

$$
\begin{equation*}
\lg K_{a}=\lg \left\{\mathrm{H}^{+}\right\}+\lg \left[\mathrm{A}^{-}\right]-\lg [\mathrm{HA}] \tag{2.9}
\end{equation*}
$$

The negative decadic logarithm of the acidity constant is then abbreviated by

$$
\begin{equation*}
\mathrm{pK}_{a}=-\lg K_{a} \tag{2.10}
\end{equation*}
$$

which parallels the definition of pH as $\mathrm{pH}=-\lg \left\{\mathrm{H}^{+}\right\}$. With $\mathrm{pK}_{a}$, Eq (2.9) converts to

$$
\begin{equation*}
\mathrm{pK}_{a}=\mathrm{pH}-\lg \left[\mathrm{A}^{-}\right]+\lg [\mathrm{HA}] \tag{2.11}
\end{equation*}
$$

## Henderson-Hasselbach Equation

Eq (2.11) can also be written as the so-called Henderson-Hasselbach equation:

$$
\begin{equation*}
\mathrm{pH}=\mathrm{pK}_{a}+\lg \frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}=\mathrm{pK}_{a}+\lg \frac{[\text { proton acceptor }]}{[\text { proton donor }]} \tag{2.12}
\end{equation*}
$$

Here, the term $\lg \left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ vanishes for equal concentrations. In other words, the $\mathrm{pK}_{a}$ value is just the pH at which the amount of both species is equal, i.e. at which $50 \%$ of the species HA is dissociated into species $\mathrm{A}^{-}$. Therefore, it is no surprise that the $\mathrm{pK}_{a}$ value is also called the "semi-equivalence point" - more on this topic in §3.2.2 and particularly in (3.44) below.

The $\mathrm{pK}_{a}$ value allows a classification into strong and weak acids: the smaller the $\mathrm{pK}_{a}$, the stronger the acid - quite the opposite to a $K_{a}$-based ranking (cf. (2.18) below).

## Gibbs Energy

In chemical thermodynamics, there is a fundamental link between the equilibrium constant $K$ and the (change of) GibBS energy:

$$
\begin{equation*}
\Delta G^{0}=-R T \ln K \tag{2.13}
\end{equation*}
$$

where $R=8.314 \mathrm{~J} /(\mathrm{mol} \cdot$ Kelvin) is the gas constant and $T$ the temperature in Kelvin. This equation can be rearranged to $\lg K$ :

$$
\begin{equation*}
\lg K=-\frac{\Delta G^{0}}{\ln 10 \cdot R T}=-\frac{\Delta G^{0}}{2.303 \cdot R T} \quad \text { or } \quad \mathrm{pK}_{a}=\frac{\Delta G^{0}}{2.303 \cdot R T} \tag{2.14}
\end{equation*}
$$

An example for the relationship between $\Delta G^{0}$ and several pK values (of a triprotic acid) is given in Fig 3.1 on page 20.

### 2.1.3 Mono-, Di-, and Triprotic Acids

Acids can donate one, two, or more protons $\mathrm{H}^{+}$. Typical examples are listed in Table 2.1.

Table 2.1: Typical mono-, di-, and triprotic acids.

| monoprotic acid (HA) | diprotic acid $\left(\mathrm{H}_{2} \mathrm{~A}\right)$ | triprotic acid $\left(\mathrm{H}_{3} \mathrm{~A}\right)$ |
| :--- | :--- | :--- |
| HCl | $\mathrm{H}_{2} \mathrm{CO}_{3}$ | $\mathrm{H}_{3} \mathrm{PO}_{4}$ |
| HNO | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | $\mathrm{H}_{3} \mathrm{AsO}_{4}$ |
| HI | $\mathrm{H}_{2} \mathrm{CrO}_{4}$ | citric acid |
| HF | $\mathrm{H}_{2} \mathrm{SeO}_{4}$ |  |
| formic acid | oxalic acid |  |

A monoprotic acid is characterized by a single acidity constant $K_{1}\left(=K_{a}\right)$, a diprotic acid by two acidity constants $\left(K_{1}, K_{2}\right)$, and a triprotic acid by three acidity constants $\left(K_{1}, K_{2}\right.$, and $\left.K_{3}\right)$ :

$$
\begin{array}{lll}
1^{\text {st }} \text { dissociation step: } & \mathrm{H}_{3} \mathrm{~A}=\mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{~A}^{-} & K_{1} \\
2^{\text {nd }} \text { dissociation step: } & \mathrm{H}_{2} \mathrm{~A}^{-}=\mathrm{H}^{+}+\mathrm{HA}^{-2} & K_{2} \\
3^{\text {rd }} \text { dissociation step: } & \mathrm{HA}^{-2}=\mathrm{H}^{+}+\mathrm{A}^{-3} & K_{3} \tag{2.17}
\end{array}
$$

## Ranking

Protons are released sequentially one after the other, with the first proton being the fastest and most easily lost, then the second, and then the third (which is the most strongly bound). This yields the following ranking of acidity constants of a polyprotic acid: ${ }^{2}$

$$
\begin{equation*}
K_{1}>K_{2}>K_{3} \quad \text { or } \quad \mathrm{pK}_{1}<\mathrm{pK}_{2}<\mathrm{pK}_{3} \tag{2.18}
\end{equation*}
$$

For example, phosphoric acid has $\mathrm{pK}_{1}=2.15, \mathrm{pK}_{2}=7.21$, and $\mathrm{pK}_{3}=12.35$. Other examples for acidity constants are listed in Table 2.2.

Table 2.2: pK values of four common $N$-protic acids at $25^{\circ} \mathrm{C}$.

| $N$ | acid | formula | type | $\mathrm{pK}_{1}$ | $\mathrm{pK}_{2}$ | $\mathrm{pK}_{3}$ | Ref |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | acetic acid | $\mathrm{CH}_{3} \mathrm{COOH}$ | HA | 4.76 |  |  | $[38]$ |
| 2 | (composite) carbonic acid | $\mathrm{H}_{2} \mathrm{CO}_{3}$ | $\mathrm{H}_{2} \mathrm{~A}$ | 6.35 | 10.33 |  | $[39]$ |
| 3 | phosphoric acid | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | $\mathrm{H}_{3} \mathrm{~A}$ | 2.15 | 7.21 | 12.35 | $[38]$ |
| 3 | citric acid | $\mathrm{C}_{6} \mathrm{H}_{8} \mathrm{O}_{7}$ | $\mathrm{H}_{3} \mathrm{~A}$ | 3.13 | 4.76 | 6.4 | $[38]$ |

Note 1. In Table 2.2, the composite carbonic acid is the sum of the unionized species $\mathrm{CO}_{2}(\mathrm{aq})$ and the pure acid: $\mathrm{H}_{2} \mathrm{CO}_{3}^{*}=\mathrm{CO}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{CO}_{3}$; to simplify the notation, we omit the asterisk $\left({ }^{*}\right)$ on $\mathrm{H}_{2} \mathrm{CO}_{3}^{*}$ throughout the text.

Note 2. The acids in the table are so-called "common acids". Additionally, there are also zwitterionic acids (amino acids). The latter are described in [1].

[^2]
### 2.1.4 Strong Acids vs Weak Acids

## Monoprotic Acids

Unlike weak acids, strong acids dissociate completely in water. Let us consider a monoprotic acid specified by $K_{a}$ and the amount $C_{T} \equiv[\mathrm{HA}]_{\mathrm{T}}$ (which is de facto the acid's initial concentration before it dissolves). In the equilibrium state, the total concentration splits into an undissociated and a dissociated part:

$$
\begin{equation*}
C_{T}=[\mathrm{HA}]+\left[\mathrm{A}^{-}\right] \quad \text { or } \quad 1=a_{0}+a_{1} \tag{2.19}
\end{equation*}
$$

where $a_{0}=[\mathrm{HA}] / C_{T}$ and $a_{1}=\left[\mathrm{A}^{-}\right] / C_{T}$ are the "ionization fractions". The difference between strong and weak acids is summarized in Table 2.3.

Table 2.3: Strong vs weak acids (greatly simplified).

|  | strong acid | weak acid |
| :--- | :---: | :---: |
| acidity constant | $K_{a} \gg 1$ | $K_{a} \leq 1$ |
| $\mathrm{pK}_{a}=-\lg K_{a}$ | $\mathrm{pK}_{a}<0$ | $\mathrm{pK}_{a}>0$ |
| $\left\{\mathrm{H}^{+}\right\} \simeq\left[\mathrm{H}^{+}\right]=10^{-\mathrm{pH}}$ | $\left[\mathrm{H}^{+}\right] \simeq C_{T}$ | $\left[\mathrm{H}^{+}\right] \ll C_{T}$ |
| undissociated acid | $[\mathrm{HA}] \simeq 0$ or $a_{0} \simeq 0$ | $[\mathrm{HA}] \simeq C_{T}$ or $a_{0} \simeq 1$ |
| dissociated acid | $\left[\mathrm{A}^{-}\right] \simeq C_{T}$ or $a_{1} \simeq 0$ | $\left[\mathrm{~A}^{+}\right] \ll C_{T}$ or $a_{1} \ll 1$ |

Figure 2.1: Undissociated fraction $a_{0}$ for strong and weak acids. Strong acids are completely dissociated in the pH range above $\mathrm{pH} \simeq 0$.

## Polyprotic Acids

The classification in Table 2.3 can also be applied to $N$-protic acids if we rename the acidity constant $K_{a}$ by the $1^{\text {st }}$ dissociation constant $K_{1}$.

## Undissociated Fraction

Weak acids are characterized by a non-negligible amount of undissolved acid. Mathematically, the undissociated part is equivalent to the ionization fraction $a_{0}$ :

$$
\begin{equation*}
\text { undissociated acid: } \quad a_{0} \equiv \frac{\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]}{C_{T}} \simeq \frac{1}{1+K_{a} / x} \quad \text { with } x=10^{-\mathrm{pH}} \tag{2.20}
\end{equation*}
$$

This quantity as a function of pH is displayed in Fig 2.1 for several acids. As expected, strong acids are completely dissociated in real-world applications (where $\mathrm{pH} \geq 0$ ). The small circles mark the position of the corresponding $\mathrm{pK}_{1}$ values (which are the inflection points of $a_{0}$ ).

### 2.1.5 Weak Acids vs Dilute Acids

A weak acid and a dilute acid are two different things. The first relies on the acidity constants $K_{a}$ (which is a thermodynamic property of the acid that nobody can change), while the second relies on the amount $C_{T}$ of a given acid:

$$
\begin{array}{ll}
\text { weak acid } \leftrightarrow \text { strong acid } & \Leftrightarrow \text { small } K_{a} \leftrightarrow \text { large } K_{a} \\
\text { dilute acid } \leftrightarrow \text { concentrated acid } & \Leftrightarrow \text { small } C_{T} \leftrightarrow \text { large } C_{T}
\end{array}
$$

One cannot make a weak acid strong, but one can change the degree of dilution (or concentration). Table 2.4 summarizes the principal difference between the degree of strength and the degree of dilution. The basic idea behind this is also sketched in Fig 2.2. For polyprotic acids, replace $K_{a}$ by $K_{1}$.

Table 2.4: Degree of strength vs degree of dilution.

|  | degree of strength | degree of dilution |
| :--- | :---: | :---: |
| determined by: | acidity constant $K_{a}$ | amount of acid $C_{T}$ |
| relationships: | weak acid $\leftrightarrow$ strong acid | dilute acid $\leftrightarrow$ concentr. acid |
|  | small $K_{a} \leftrightarrow$ large $K_{a}$ | small $C_{T} \leftrightarrow$ large $C_{T}$ |
| (positive $\mathrm{pK}_{a} \leftrightarrow$ negative $\mathrm{pK}_{a}$ |  |  |
| compares: | two different acids | dilution of the same acid |
| describes: | release of $\mathrm{H}^{+}$ | dilution of $\mathrm{H}^{+}$ |
| type: | fundamental property | control parameter |
|  | (cannot be changed) | (can be changed) |

### 2.2 Basic Set of Equations

### 2.2.1 Special Case: Diprotic Acids $\left(\mathrm{H}_{2} \mathrm{~A}\right)$

Before turning to $N$-protic acids, let us start with the simple case of diprotic acids $(N=2)$.

Figure 2.2: Weak/strong vs dilute/concentrated acid.

When a diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ (the solute) is added to pure water (the solvent), the equilibrium state of the solution is characterized by five dissolved species: $\mathrm{H}^{+}$, $\mathrm{OH}^{-}, \mathrm{H}_{2} \mathrm{~A}, \mathrm{HA}^{-}$, and $\mathrm{A}^{-2}$ (see Fig 2.3). Thus, five equations are required for its math description:

$$
\begin{align*}
K_{w} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{OH}^{-}\right\} & & \text {(self-ionization of } \left.\mathrm{H}_{2} \mathrm{O}\right)  \tag{2.21}\\
K_{1} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{HA}^{-}\right\} /\left\{\mathrm{H}_{2} \mathrm{~A}\right\} & & \left(1^{\text {st }}\right. \text { dissociation step) }  \tag{2.22}\\
K_{2} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{A}^{-2}\right\} /\left\{\mathrm{HA}^{-}\right\} & & \left(2^{\text {nd }}\right. \text { dissociation step) }  \tag{2.23}\\
C_{T} & =\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right]+\left[\mathrm{A}^{-2}\right] & & \text { (mass balance) }  \tag{2.24}\\
0 & =\left[\mathrm{HA}^{-}\right]+2\left[\mathrm{~A}^{-2}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] & & \text {(charge balance) } \tag{2.25}
\end{align*}
$$

The first three equations are mass-action laws (of type (2.6)); the two last equations represent the mass balance and the charge balance. While the mass-action laws are based on activities (denoted by braces), the mass-balance and charge-balance equations rely on molar concentrations (denoted by square brackets) - see Fig 2.4.

Figure 2.3: Addition of a diprotic acid to water results in an equilibrium state with five species.

Note. The total concentration of a diprotic acid is abbreviated by $C_{T}=\left[\mathrm{H}_{2} \mathrm{~A}\right]_{\mathrm{T}}$. This quantity should not be confused with the neutral dissolved species $\mathrm{H}_{2} \mathrm{~A}(\mathrm{aq})$ and its molar concentration $\left[\mathrm{H}_{2} \mathrm{~A}\right] .^{3}$

As summarized in Fig 2.5, the math description of the diprotic acid system is based on two components (or subsystems) plus a coupling term:

[^3]```
K
K
K
based on activities \{..\}
```

Figure 2.4: Diprotic acid: activity-based equations vs concentration-based equations.

## mass balance

based on concentrations [..]

$$
\mathrm{C}_{\mathrm{T}}=\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right]+\left[\mathrm{A}^{-2}\right]
$$

charge balance

$$
0=\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]-\left[\mathrm{HA}^{-}\right]-2\left[\mathrm{~A}^{-2}\right]
$$

- component $\mathrm{H}_{2} \mathrm{O}$ (subsystem "pure water") described by (2.21)
- component $\mathrm{H}_{2} \mathrm{~A}$ (subsystem "acid") described by (2.22) to (2.24)
- coupling of both subsystems described by (2.25)

The two subsystems are linked together by the charge-balance equation (2.25).

Figure 2.5: Diprotic-acid system: The subsystem " $\mathrm{H}_{2} \mathrm{O}$ " and the subsystem "acid" are coupled by the charge-balance equation.

$$
\begin{gathered}
\text { pure } \mathrm{H}_{2} \mathrm{O} \\
\mathrm{~K}_{\mathrm{w}}=\left\{\mathrm{H}^{+}\right\}\left\{\mathrm{OH}^{-}\right\}
\end{gathered}
$$

diprotic acid

$$
\mathrm{K}_{1}=\left\{\mathrm{H}^{+}\right\}\left\{\mathrm{HA}^{-}\right\} /\left\{\mathrm{H}_{2} \mathrm{~A}\right\}
$$

$$
K_{2}=\left\{H^{+}\right\}\left\{A^{-2}\right\} /\left\{H A^{-}\right\}
$$

$$
C_{T}=\left[H_{2} A\right]+[H A-]+\left[\mathrm{A}^{-2}\right]
$$

$$
0=\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]-\left[\mathrm{HA}^{-}\right]-2\left[\mathrm{~A}^{-2}\right]
$$

charge balance

### 2.2.2 General Case: Polyprotic Acids $\left(\mathrm{H}_{\mathrm{N}} \mathrm{A}\right)$

Given is an $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$. It is characterized by

$$
N+3 \text { species (variables): } \mathrm{H}^{+}, \mathrm{OH}^{-}, \underbrace{\mathrm{H}_{\mathrm{N}} \mathrm{~A}, \mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}, \ldots, \mathrm{A}^{-\mathrm{N}}}_{N+1 \text { acid species }}
$$

Hence, a complete math description requires a set of $N+3$ equations:

$$
\begin{array}{rlrl}
K_{w} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{OH}^{-}\right\} & & \text {(self-ionization } \left.\mathrm{H}_{2} \mathrm{O}\right) \\
K_{1} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right\} /\left\{\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right\} & & \left(1^{\text {st }}\right. \text { diss step) } \\
K_{2} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right\} /\left\{\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right\} & & \left(2^{\text {nd }} \text { diss step }\right) \\
\vdots & & \\
K_{N} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{A}^{-\mathrm{N}}\right\} /\left\{\mathrm{HA}^{-(\mathrm{N}-1)}\right\} & & \left(\mathrm{N}^{\text {th }} \text { diss step }\right) \\
C_{T} & =\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]+\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+\ldots+\left[\mathrm{A}^{-\mathrm{N}}\right] & & (\text { mass balance }) \\
0 & =\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+2\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right]+\ldots+N\left[\mathrm{~A}^{-\mathrm{N}}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \tag{2.31}
\end{array}
$$

Here the last equation represents the charge balance.
The math structure is analogous to that of diprotic acids in $\S 2.2 .1$. All massaction laws, i.e. the first $N+1$ equations, are based on activities, $\{j\}$, while the mass balance and charge balance, i.e. the last two equations, are based on molar concentrations, $[j]$.

This set of equations represents an exact description of the $N$-protic acid; however, due to the presence of activities in the mass-action formulas (requiring activity models as a prerequisite), this set of equations can only be solved numerically (with the computer).

## Preconditions for Analytical Formulas

In order to deduce closed-form expressions (i.e. analytical formulas), we have to replace all activities by molar concentrations (except for $\mathrm{H}^{+}$):

$$
\{j\} \longrightarrow[j]
$$

This approximation is valid either in very dilute systems or by using conditional equilibrium constants ${ }^{c} K$ as introduced in (2.7). In the following we assume that this has been done (without explicitly specifying it by ${ }^{c} K$ in the notation). Thus we have for the system of $N+3$ equations:

$$
\begin{array}{rlrl}
K_{w} & =\left\{\mathrm{H}^{+}\right\} \cdot\left[\mathrm{OH}^{-}\right] & & \text {(self-ionization } \left.\mathrm{H}_{2} \mathrm{O}\right) \\
K_{1} & =\left\{\mathrm{H}^{+}\right\} \cdot\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right] & & \left(1^{\text {st }} \text { diss step }\right) \\
K_{2} & =\left\{\mathrm{H}^{+}\right\} \cdot\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right] /\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] & & \left(2^{\text {nd }}\right. \text { diss step) } \\
\vdots & & \\
K_{N} & =\left\{\mathrm{H}^{+}\right\} \cdot\left[\mathrm{A}^{-\mathrm{N}}\right] /\left[\mathrm{HA}^{-(\mathrm{N}-1)}\right] & & \\
C_{T} & =\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]+\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+\ldots+\left[\mathrm{A}^{-\mathrm{N}}\right] & & (\text { mass balance }) \\
0 & =\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+2\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right]+\ldots+N\left[\mathrm{~A}^{-\mathrm{N}}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \tag{2.37}
\end{array}
$$

Comparing this to the set of equations (2.26) to (2.31), the mass and charge balance (i.e. the last two equations) remain unchanged. And as for the rest of the equations, you have to look closely to see the small but so fundamental change: the transition from activities to concentrations (by changing the type of brackets).

The new set of equations is the basis for all subsequent investigations. As a warm-up, the next paragraph starts with the subset of equations (2.33) to (2.36) that defines the 1-component subsystem "acid". It exhibits the math features of the acid in its clearest form.

Things will seem difficult when simple and simple when difficult. The intelligent understand this and maintain control through manipulation.

### 3.1 The Subsystem "Pure Acid"

This Chapter focuses on the 1-component system "acid" defined by the subset of $N+1$ equations (2.33) to (2.36). In other words, we ignore the self-ionization of water in (2.32) and the charge balance equation (2.37).

### 3.1.1 Streamlined Notation

Given is an $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ with the total amount (molar concentration)

$$
\begin{equation*}
C_{T} \equiv\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]_{\mathrm{T}}=\operatorname{TOT} \mathrm{H}_{\mathrm{N}} \mathrm{~A} \tag{3.1}
\end{equation*}
$$

The $N$-protic acid is characterized by $N+1$ species:
$\begin{array}{ll}1 \text { undissociated species: } & \mathrm{H}_{\mathrm{N}} \mathrm{A}(\mathrm{aq}) \\ N \text { dissociated species: } & \mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-1}, \ldots, \mathrm{HA}^{-(\mathrm{N}-1)}, \mathrm{A}^{-\mathrm{N}}\end{array} \begin{aligned} & \text { (electro-neutral) } \\ & \text { (anionic) }\end{aligned}$
To simplify the notation, we abbreviate the molar concentrations of the dissolved species with

$$
\begin{equation*}
[j] \equiv\left[\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{~A}^{-\mathrm{j}}\right] \quad \text { for } j=0,1,2, \ldots, N \tag{3.2}
\end{equation*}
$$

The symbol $j$ is an integer, which also indicates the negative charge of the species (which is equal to the number of $\mathrm{H}^{+}$released):

$$
\begin{equation*}
z_{j}=0-j \tag{3.3}
\end{equation*}
$$

Thus, the species [0] stands for the uncharged, undissociated compound $H_{N} A(a q)$. Note: This quantity should not be confused with the acid's total amount, $\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]_{\mathrm{T}}$.

The sum of all species yields the total concentration $C_{T}$ :

$$
\begin{equation*}
\text { mass balance: } \quad C_{T}=\sum_{j=0}^{N}[j]=[0]+[1]+\cdots+[N] \tag{3.4}
\end{equation*}
$$

## Dissociation Steps

In each successive dissociation step, $j$ is enhanced by 1 (due to the release of one $\mathrm{H}^{+}$ion):

$$
\begin{equation*}
\mathrm{j}^{\text {th }} \text { dissociation step: } \quad[j-1] \longrightarrow[j] \tag{3.5}
\end{equation*}
$$

where, according to (2.4), the conjugate acid-base pair is composed of:

$$
\left.\begin{array}{ll}
\text { acid: } & {[j-1]}  \tag{3.6}\\
\text { conjugate base: } & {[j]}
\end{array}\right\} \quad \text { of the } \mathrm{j}^{\text {th }} \text { dissociation step }
$$

## Ionization Fractions

Instead of using the $N+1$ acid species $[j]$, it is more convenient to work with ionization fractions (as the ratio of the acid-species concentration to the total amount of acid):

$$
\begin{equation*}
a_{j} \equiv \frac{[j]}{C_{T}} \quad \text { for } j=0,1,2, \ldots, N \tag{3.7}
\end{equation*}
$$

### 3.1.2 Stepwise vs Cumulative Dissociation

As we know from § 2.1.3, a monoprotic acid is characterized by one acidity constant $K_{1}\left(=K_{a}\right)$, a diprotic acid by two acidity constants $\left(K_{1}, K_{2}\right)$, and a triprotic acid by three acidity constants $\left(K_{1}, K_{2}\right.$, and $\left.K_{3}\right)$ :

| $1^{\text {st }}$ dissociation step: | $\mathrm{H}_{3} \mathrm{~A}=\mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{~A}^{-}$ | $K_{1}$ |
| :--- | :--- | :--- |
| $2^{\text {nd }}$ dissociation step: | $\mathrm{H}_{2} \mathrm{~A}^{-}=\mathrm{H}^{+}+\mathrm{HA}^{-2}$ | $K_{2}$ |
| $3^{\text {rd }}$ dissociation step: | $\mathrm{HA}^{-2}=\mathrm{H}^{+}+\mathrm{A}^{-3}$ | $K_{3}$ |

The three reactions can also be written as:

$$
\begin{array}{ll}
\mathrm{H}_{3} \mathrm{~A}=\mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{~A}^{-} & k_{1}=K_{1} \\
\mathrm{H}_{3} \mathrm{~A}=2 \mathrm{H}^{+}+\mathrm{HA}^{-2} & k_{2}=K_{1} K_{2} \\
\mathrm{H}_{3} \mathrm{~A}=3 \mathrm{H}^{+}+\mathrm{A}^{-3} & k_{3}=K_{1} K_{2} K_{3} \tag{3.13}
\end{array}
$$

with $k_{j}$ as the cumulative acidity constants.

So we have two types of representation: The first representation describes the step-by-step release of a single $\mathrm{H}^{+}$in each dissociation step (it's the way nature works); the second relates each dissociated species to the undissociated acid by a "manyproton" or cumulative release. The latter is a math trick to simplify calculations.

The second representation (in Table 3.1) requires a new set of mass-action laws based on cumulative acidity constants $k_{1}, k_{2}$, to $k_{N}$ :

$$
\left.\begin{array}{rl}
K_{1} & =\left\{\mathrm{H}^{+}\right\}\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right] \\
K_{2} & =\left\{\mathrm{H}^{+}\right\}\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right] /\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] \\
& \vdots \\
K_{N} & =\left\{\mathrm{H}^{+}\right\}\left[\mathrm{A}^{-\mathrm{N}}\right] /\left[\mathrm{HA}^{-(\mathrm{N}-1)}\right]
\end{array}\right\} \Rightarrow \begin{aligned}
k_{1} & =\left\{\mathrm{H}^{+}\right\}\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right] \\
k_{2} & =\left\{\mathrm{H}^{+}\right\}^{2}\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right] \\
& \vdots \\
k_{N} & =\left\{\mathrm{H}^{+}\right\}^{N}\left[\mathrm{~A}^{-\mathrm{N}}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]
\end{aligned}
$$

which are products of $K_{1}, K_{2}$, and so on:

$$
k_{j}= \begin{cases}1 & \text { for } j=0  \tag{3.14}\\ K_{1} K_{2} \cdots K_{j} & \text { for } 1 \leq j \leq N\end{cases}
$$

For values of $j$ outside this range (i.e. either for negative $j$ or for $j>N$ ), we set $k_{j}=0$. In logarithmic form, using the definition $\mathrm{pk}_{j} \equiv-\lg k_{j}$, it becomes:

$$
\mathrm{pk}_{j}= \begin{cases}1 & \text { for } \quad j=0  \tag{3.15}\\ \mathrm{pK}_{1}+\mathrm{pK}_{2}+\cdots+\mathrm{pK}_{j} & \text { for } 1 \leq j \leq N\end{cases}
$$

This additive relationship is illustrated in Fig 3.1 for the triprotic acid, where the $\mathrm{pk}_{j}$ and $\mathrm{pK}_{j}$ values are plotted along a GIBBS energy axis.

Table 3.1: Acid species and their cumulative acidity constants (in the new representation).

| $j$ | species | equilibrium reaction | cumulative acidity constant |  |
| :--- | :--- | :--- | :--- | :--- |
| 0 | $[0] \equiv\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]$ | $\mathrm{H}_{\mathrm{N}} \mathrm{A}=\mathrm{H}_{\mathrm{N}} \mathrm{A}$ | $k_{0}=\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]$ | $=1$ |
| 1 | $[1] \equiv\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]$ | $\mathrm{H}_{\mathrm{N}} \mathrm{A}=\mathrm{H}^{+}+\mathrm{H}_{\mathrm{N}} \mathrm{A}^{-}$ | $k_{1}=\left\{\mathrm{H}^{+}\right\}\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]=K_{1}$ |  |
| 2 | $[2] \equiv\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right]$ | $\mathrm{H}_{\mathrm{N}} \mathrm{A}=2 \mathrm{H}^{+}+\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}$ | $k_{2}=\left\{\mathrm{H}^{+}\right\}^{2}\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]=K_{1} K_{2}$ |  |
| $\vdots$ |  |  |  |  |
| $N$ | $[N] \equiv\left[\mathrm{A}^{-\mathrm{N}}\right]$ | $\mathrm{H}_{\mathrm{N}} \mathrm{A}=N \mathrm{H}^{+}+\mathrm{A}^{-\mathrm{N}}$ | $k_{N}=\left\{\mathrm{H}^{+}\right\}^{N}\left[\mathrm{~A}^{-\mathrm{N}}\right] /\left[\mathrm{H}_{\mathrm{N}} \mathrm{A}\right]=K_{1} K_{2} \cdots K_{N}$ |  |

In contrast to the $\mathrm{pk}_{j}$ values, which are arranged on the energy scale (like in Fig 3.1), the $\mathrm{pK}_{j}$ values can be arranged on a pH scale - see Fig 3.2 on page 25.

Note. The cumulative acidity constant $k_{j}$ should not be confused with the cumulative equilibrium constant for complex formation denoted by $\beta_{j}$ (stability constants). Acidity constants are dissociation constants, while complex-formation constants are association constants. For more details see [1].

Figure 3.1: Relationship between pk and pK values of a triprotic acid on a Gibbs-energy axis.

### 3.1.3 Generalized Henderson-Hasselbach Equations

The two representations (i.e. the stepwise and the cumulative dissociation introduced in §3.1.2) can be brought into a compact form (using $x=\left\{\mathrm{H}^{+}\right\}$):
reaction formula law-of-mass action

$$
\begin{array}{lll}
\text { stepwise: } & \mathrm{H}_{\mathrm{N}-(\mathrm{j}-1)} \mathrm{A}^{-(\mathrm{j}-1)}=\mathrm{H}^{+}+\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{~A}^{-\mathrm{j}} & K_{j}=\frac{x[j]}{[j-1]} \\
\text { cumulative: } & \mathrm{H}_{\mathrm{N}} \mathrm{~A}=\mathrm{jH}^{+}+\mathrm{H}_{\mathrm{N}-\mathrm{j}} \mathrm{~A}^{-\mathrm{j}} & k_{j}=\frac{x^{j}[j]}{[0]}=K_{1} K_{2} \cdots K_{j} \tag{3.17}
\end{array}
$$

Here, (3.16) represents the $j^{\text {th }}$ dissociation step characterized by $K_{j}$; these are $N$ reactions (where $j$ runs from 1 to $N$ ). In (3.17), the number of reactions is $N+1$ (where $j$ runs from 0 to $N$ ), including the trivial case $\mathrm{H}_{\mathrm{N}} \mathrm{A}=\mathrm{H}_{\mathrm{N}} \mathrm{A}$ with $k_{0}=1$.

Eqs (3.16) and (3.17) provide the pH (or $x$ ) at particular concentration ratios:

$$
\begin{array}{lll}
\frac{[j]}{[j-1]}=\frac{K_{j}}{x} & \xrightarrow[{[j]=[j-1}]]{\longrightarrow} & x=K_{j} \\
\frac{[j+1]}{[j-1]}=\frac{K_{j}}{x} \frac{K_{j+1}}{x} & \xrightarrow{[j+1]=[j-1]} & x=\left(K_{j} K_{j+1}\right)^{1 / 2} \\
\frac{[j]}{[0]}=\frac{k_{j}}{x^{j}}=\frac{K_{1}}{x} \frac{K_{2}}{x} \cdots \frac{K_{j}}{x} & \tag{3.20}
\end{array}
$$

Thus, once we know the concentration of one species, say $[j]$, we are able to calculate all other concentrations in turn, i.e. the equilibrium distribution of all species for a given pH (or $x$ ). Under specific conditions (indicated by the arrows) the first two equations define two types of equivalence points, which will be discussed in § 3.2.1.

In logarithmic form, the first two equations are generalizations of the HendersonHasselbach formula introduced in (2.12):

$$
\begin{array}{lll}
\mathrm{pH}=\mathrm{pK}_{\mathrm{j}}+\lg \frac{[j]}{[j-1]} & \xrightarrow{[j]=[j-1]} & \mathrm{pH}=\mathrm{pK}_{\mathrm{j}} \\
\mathrm{pH}=\frac{\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}}{2}+\lg \frac{[j+1]}{[j-1]} & \xrightarrow{[j+1]=[j-1]} & \mathrm{pH}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right)
\end{array}
$$

### 3.1.4 Closed-Form Expressions

Using (3.17), the subset of the $N+1$ equations (2.33) to (2.36) collapses to:

$$
\begin{array}{ll}
{[j]=\left(\frac{k_{j}}{x^{j}}\right)[0]} & (N \text { dissociation steps, } j=1 \text { to } N) \\
C_{T}=\sum_{j=0}^{N}[j]=[0] \sum_{j=0}^{N} \frac{k_{j}}{x^{j}} \quad \text { (mass balance) } \tag{3.24}
\end{array}
$$

As long as we consider the subsystem "acid" alone, $C_{T}$ itself is irrelevant. ${ }^{1}$ Dividing both equations by $C_{T}$, we obtain the ionization fractions defined by $a_{j}=[j] / C_{T}$ :

$$
\begin{align*}
& a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0}  \tag{3.25}\\
& 1=\sum_{j=0}^{N} a_{j}=a_{0} \sum_{j=0}^{N} \frac{k_{j}}{x^{j}}=a_{0}\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right) \tag{3.26}
\end{align*}
$$

The last equation provides a formula for $a_{0}$ as a function of $x(\mathrm{or} \mathrm{pH})$ :

$$
\begin{align*}
a_{0} & =\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right)^{-1}  \tag{3.27}\\
& =\left(1+\frac{K_{1}}{x}+\frac{K_{1} K_{2}}{x^{2}}+\cdots+\frac{K_{1} K_{2} \cdots K_{N}}{x^{N}}\right)^{-1} \tag{3.28}
\end{align*}
$$

If $a_{0}$ is known, all other ionization fractions $a_{j}$ can be calculated from (3.25). The set of ionization fractions - i.e. the normalized acid-species distribution - contains the complete information about the subsystem "acid". The fascinating features of the ionization fractions will be discussed and presented in § 3.3.

## Summary

Given $x\left(=10^{-\mathrm{pH}}\right)$, the species distribution of the subsystem "acid" is completely determined by the set of $N+1$ ionization fractions (for $j=0,1, \ldots, N$ ):

$$
\begin{equation*}
a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0} \quad \text { with } \quad a_{0}=\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right)^{-1} \tag{3.29}
\end{equation*}
$$

### 3.1.5 Inverse Task

The inverse task is to calculate $x$ or pH starting from a given $a_{0}$ (or any other $a_{j}$ ). Unfortunately, the inverse task does not hold a simple equation in store for us. On the contrary, it leads to a polynomial of high degree, namely of degree $N$ (as derived in Appendix B.1.1):

$$
\begin{equation*}
0=\text { const } \cdot x^{N-j} \sum_{i \neq j}^{N} k_{i} x^{N-i} \quad \text { with } \quad \text { const }=-\left(\frac{1-a_{j}}{a_{j}}\right) k_{j} \tag{3.30}
\end{equation*}
$$

[^4]If we move from the 1-component system "acid" to the 2-component system "acid $+\mathrm{H}_{2} \mathrm{O}$ ", the degree of the polynomial increases to $N+2$, as it will be shown in (4.11) below.

## Special Case: $\mathbf{H}_{\mathbf{2}} \mathbf{A}$

For a diprotic acid $\mathrm{H}_{2} \mathrm{~A}$, (3.30) becomes a quadratic equation (which can be solved easily). Let's assume we know the value of $a_{0}$ and want to calculate the corresponding $x$. The steps are as follows (note that $k_{0}=1$ ):

$$
\begin{align*}
& 0=-\left(\frac{1-a_{0}}{a_{0}}\right) x^{2}+K_{1} x+K_{1} K_{2}  \tag{3.31}\\
& 0=x^{2}-\alpha K_{1} x-\alpha K_{1} K_{2} \quad \text { with } \quad \alpha=\frac{a_{0}}{1-a_{0}} \tag{3.32}
\end{align*}
$$

The positive root of this quadratic equation is

$$
\begin{equation*}
x=\frac{\alpha K_{1}}{2}\left(1+\sqrt{1+\frac{4}{\alpha} \frac{K_{2}}{K_{1}}}\right) \tag{3.33}
\end{equation*}
$$

Usually $K_{2} / K_{1} \ll 1$ applies, so that the second term inside the square root disappears. Then, for $a_{0}=\frac{1}{2}$ (i.e. $\alpha=1$ ) we obtain the simple result: $x=K_{1}$.

### 3.2 Equivalence Points

### 3.2.1 Definition of Equivalence Points

An equivalence point (EP) is a special equilibrium state at which chemically equivalent quantities of acid and base have been mixed:

$$
\begin{equation*}
\text { equivalence point: } \quad[\text { acid }]=[\text { base }] \tag{3.34}
\end{equation*}
$$

This concept applies to any conjugate acid-base pair:

$$
\begin{equation*}
\text { equivalence point: } \quad[\text { acid }]=[\text { conjugate base }] \tag{3.35}
\end{equation*}
$$

Thus, a polyprotic acid gives rise to a whole series of EPs, because - as we have seen in (3.5) to (3.6) - each dissociation step (by releasing 1 proton) relates an acid species to its conjugate base. Thereby, two types of equivalence points emerge:

$$
\begin{array}{ll}
\mathrm{EP}_{\mathrm{j}}: & {[j-1]=[j+1]} \\
\operatorname{semi}-\mathrm{EP}_{\mathrm{j}}: & {[j-1]=[j]}
\end{array}
$$

The definition of $\mathrm{EP}_{\mathrm{j}}$ applies for $j=0$ and $j=N$ too, if we extend our notation and identify $[-1]$ by $\left[\mathrm{H}^{+}\right]$and $[N+1]$ by $\left[\mathrm{OH}^{-}\right]$. Taken together, it yields:

$$
\begin{array}{lll}
\mathrm{EP}_{0}: & {\left[\mathrm{H}^{+}\right]=[1]} & (\text { for } j=0) \\
\mathrm{EP}_{\mathrm{j}}: & {[j-1]=[j+1]} & (\text { for } j=1,2, \ldots, N) \\
\mathrm{EP}_{\mathrm{N}}: & {[N-1]=\left[\mathrm{OH}^{-}\right]} & (\text {for } j=N)
\end{array}
$$

and

$$
\begin{equation*}
\text { semi-EP }{ }_{\mathrm{j}}: \quad[j-1]=[j] \quad(\text { for } j=1,2, \ldots, N) \tag{3.41}
\end{equation*}
$$

On the pH scale, each EP is the midpoint between two adjacent semi-EPs (as shown later in $\S 3.2 .2$ ). The acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ has $N+1 \mathrm{EPs}$ (the same number as the number of acid species) plus $N$ semi-EPs. In total there are $2 N+1$ equivalence points, called $\mathrm{EP}_{\mathrm{n}}$, where $n$ runs over all integer and half-integer values:

$$
\begin{equation*}
n=0, \frac{1}{2}, 1, \frac{3}{2}, 2, \ldots, N-\frac{1}{2}, N \tag{3.42}
\end{equation*}
$$

According to the equations (3.38) to (3.41), $\mathrm{EP}_{\mathrm{n}}$ is defined by

$$
\mathrm{EP}_{\mathrm{n}} \Leftrightarrow\left\{\begin{array}{ll}
{[n-1]=[n+1]} & \text { for } n=0,1,2, \ldots, N \quad \Leftrightarrow \mathrm{EP}_{j=n}  \tag{3.43}\\
{\left[n-\frac{1}{2}\right]=\left[n+\frac{1}{2}\right]} & \text { for } n=\frac{1}{2}, \frac{3}{2}, \ldots, N-\frac{1}{2}
\end{array} \Leftrightarrow \text { semi-EP }{ }_{j=n+1 / 2}\right. \text {. }
$$

Note 1. Comparing (3.36) and (3.37) based on $j$ with (3.43) based on $n$, we see that introducing $n$ makes the equations more "symmetric".

Note 2. The choice of the lowercase letter $n$ as the subscript on $E P_{n}$ is not accidental. The deep relationship between $\mathrm{EP}_{n}$ and the variable $n=C_{B} / C_{T}$, where $C_{B}$ is the amount of strong base, will be discussed in Chapter 5.

### 3.2.2 Assignment between $\mathrm{EP}_{\mathrm{n}}$ and $\mathrm{pH}_{\mathrm{n}}$

The equivalence point as a special equilibrium state is characterized by a specific pH value: $\mathrm{EP}_{\mathrm{n}} \Leftrightarrow \mathrm{pH}_{\mathrm{n}}\left(\right.$ or $\mathrm{EP}_{\mathrm{n}} \Leftrightarrow x_{n}$ ). This assignment can be easily established. But before we start, it is useful to make a distinction between so-called external and internal EPs, which separate the two outermost equivalence points $\mathrm{EP}_{0}$ and $\mathrm{EP}_{\mathrm{N}}$ from the rest:

- external equivalence points $\mathrm{EP}_{0}$ and $\mathrm{EP}_{\mathrm{N}}$ (only two)
- internal equivalence points all other $\mathrm{EP}_{n} \quad$ (for $\frac{1}{2} \leq n \leq N-\frac{1}{2}$ )

## Internal EPs

The internal equivalence points deliver particularly simple formulas. From (3.18) and (3.19), or from (3.21) and (3.22), we obtain (valid for $0<j<N$ ):

$$
\begin{array}{ll}
\text { semi- } \mathrm{EP}_{\mathrm{j}}:[j-1]=[j] \Rightarrow \mathrm{pH}=\mathrm{pK}_{\mathrm{j}} & \Leftrightarrow x=K_{j} \\
\mathrm{EP}_{\mathrm{j}}: & {[j-1]=[j+1] \Rightarrow \mathrm{pH}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right) \Leftrightarrow x=\sqrt{K_{j} K_{j+1}}} \tag{3.45}
\end{array}
$$

It gives the following sequence:

$$
\begin{array}{llll}
n=\frac{1}{2}: & \mathrm{EP}_{1 / 2} & \Leftrightarrow \mathrm{pH}_{1 / 2} & =\mathrm{pK}_{1} \\
n=1: & \mathrm{EP}_{1} & \Leftrightarrow \mathrm{pH}_{1} & =\frac{1}{2}\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}\right) \\
n=\frac{3}{2}: & \mathrm{EP}_{3 / 2} & \Leftrightarrow \mathrm{pH}_{3 / 2} & =\mathrm{pK}_{2} \\
n=2: & \mathrm{EP}_{2} & \Leftrightarrow \mathrm{pH}_{2}=\frac{1}{2}\left(\mathrm{pK}_{2}+\mathrm{pK}_{3}\right) \\
\vdots & & & \\
n=N-\frac{1}{2}: & \mathrm{EP}_{\mathrm{N}-1 / 2} & \Leftrightarrow & \mathrm{pH}_{\mathrm{N}-1 / 2}=\mathrm{pK}_{\mathrm{N}} \tag{3.50}
\end{array}
$$

Here the close relationship between equivalence points and pK values becomes evident. Each acid's pK value represents exactly one semi-EP (characterized by
half-integer $n$ ). On the other hand, $\mathrm{EP}_{\mathrm{n}}$ with integer $n$ are the midpoints between two adjacent semi-EPs. It can be summarized as follows: ${ }^{2}$

$$
\mathrm{pH}_{\mathrm{n}}=\left\{\begin{array}{lll}
\frac{1}{2}\left(\mathrm{pK}_{\mathrm{n}}+\mathrm{pK}_{\mathrm{n}+1}\right) & \text { for } n=1,2, \ldots, N-1 & \left(\mathrm{EP}_{j=n}\right)  \tag{3.51}\\
\mathrm{pK}_{\mathrm{n}+1 / 2} & \text { for } n=\frac{1}{2}, \frac{3}{2}, \ldots, N-\frac{1}{2} & \left(\operatorname{semi}^{2}-\mathrm{EP}_{j=n+1 / 2}\right)
\end{array}\right.
$$

Table 3.2 lists the internal EPs of four common acids, which are completely determined by the acid's pK values (no other information is necessary). In this respect, they differ from external EPs which depend on the amount of acid, $C_{T}$.

Table 3.2: Internal equivalence points of four acids (based on pK values in Table 2.2).

| $N$ | acid | $\mathrm{pH}_{1 / 2}$ | $\mathrm{pH}_{1}$ | $\mathrm{pH}_{3 / 2}$ | $\mathrm{pH}_{2}$ | $\mathrm{pH}_{5 / 2}$ |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| 1 | acetic acid | 4.76 |  |  |  |  |
| 2 | (composite) carbonic acid | 6.35 | 8.34 | 10.33 |  |  |
| 3 | phosphoric acid | 2.15 | 4.68 | 7.21 | 9.78 | 12.35 |
| 3 | citric acid | 3.13 | 3.94 | 4.76 | 5.58 | 6.4 |

## External EPs

There are only two external equivalence points: $\mathrm{EP}_{0}$ and $\mathrm{EP}_{\mathrm{N}}$. The formulas which refer to $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$via (3.38) or (3.40) are a bit trickier than for the internal EPs. From (3.23) to (3.27) follows: ${ }^{3}$

$$
\begin{array}{ll}
\mathrm{EP}_{0}: & {\left[\mathrm{H}^{+}\right]=[1] \quad \Rightarrow x=C_{T} a_{1} \quad \Rightarrow C_{T}=\frac{x^{2}}{K_{1}} \cdot \frac{1}{a_{0}(x)}} \\
\mathrm{EP}_{\mathrm{N}}: & {[N-1]=\left[\mathrm{OH}^{-}\right] \Rightarrow C_{T} a_{N-1}=\frac{K_{w}}{x} \Rightarrow C_{T}=\frac{K_{w} K_{N}}{x^{2}} \cdot \frac{1}{a_{N}(x)}} \tag{3.53}
\end{array}
$$

Here the pH values (or $x$ ) depend on the total amount of acid, $C_{T}$. Unfortunately, the equations on the right-hand side can only be offered as implicit functions of $x: C_{T}=C_{T}(x)$. [The inverse relationship, $x=x\left(C_{T}\right)$, would require root-solving of a high-degree polynomial.]

The only thing we can offer are values for the asymptotic case. As shown later in (3.71) and (3.72), we have $a_{0}=1$ for $x \rightarrow \infty$ and $a_{N}=1$ for $x \rightarrow 0$. The last two equations then yield:

$$
\begin{array}{llll}
\mathrm{EP}_{0}: & \text { approaching } \mathrm{pH} \rightarrow 0 & (\text { or } x \rightarrow \infty) & \text { if } C_{T} \rightarrow \infty \\
\mathrm{EP}_{\mathrm{N}}: & \text { approaching } \mathrm{pH} \rightarrow 14 & (\text { or } x \rightarrow 0) & \text { if } C_{T} \rightarrow \infty \tag{3.55}
\end{array}
$$

### 3.2.3 Summary \& Examples

The same acidity constants (or pK values) that characterize the $N$-protic acid represent the pH values of the internal equivalent points in the form of (3.43):

[^5]- EP with integer $n \quad\left(\mathrm{EP}_{1}, \mathrm{EP}_{2}, \ldots, \mathrm{EP}_{\mathrm{N}-1}\right) \quad$ at $\mathrm{pH}_{\mathrm{n}}$
- semi-EP with half-integer $n \quad\left(\mathrm{EP}_{1 / 2}, \mathrm{EP}_{3 / 2}, \ldots, \mathrm{EP}_{\mathrm{N}-1 / 2}\right)$ at $\mathrm{pK}_{\mathrm{n}+1 / 2}$

In addition, there are two external, non-constant equivalence points located at both ends of the pH scale when $C_{T} \rightarrow \infty$ :

- $\mathrm{EP}_{0}: \mathrm{pH} \rightarrow 0$
- $\mathrm{EP}_{\mathrm{N}}: \mathrm{pH} \rightarrow 14$

On the pH scale, all equivalence points $\mathrm{EP}_{\mathrm{n}}$ (external and internal) are arranged from left to right when $n$ is increased stepwise as in (3.42):

$$
\begin{equation*}
\mathrm{pH}_{0}, \mathrm{pH}_{1 / 2}, \mathrm{pH}_{1}, \mathrm{pH}_{3 / 2}, \ldots, \mathrm{pH}_{\mathrm{N}} \tag{3.56}
\end{equation*}
$$

Such a sequence is shown schematically in Fig 3.2 for the triprotic acid $\mathrm{H}_{3} \mathrm{PO}_{4}$.

Figure 3.2:
Equivalence points of a triprotic acid $\mathrm{H}_{3} \mathrm{~A}$ arranged on the pH scale.

## $\mathrm{pH}-C_{T}$ Plots

Fig 3.3 shows all equivalence points of the carbonic acid (left diagram) and the phosphoric acid (right diagram) in the $\mathrm{pH}-C_{T}$ diagram. The internal equivalence points (in red color) are independent of $C_{T}$ and therefore straight lines, the two external EPs (blue and green curves) are not.

$\mathrm{H}_{3} \mathrm{~A}$ (phosphoric acid)

Figure 3.3: pH dependence of EPs and semi-EPs for two acids plotted as $C_{T}=f(\mathrm{pH})$. The curves are approximations valid for the subsystem "acid" (i.e. without coupling to the subsystem " $\mathrm{H}_{2} \mathrm{O}$ ").

The representation as dashed curves (and not as solid lines) in Fig 3.3 reminds us that these are approximations, valid for the isolated subsystem "acid" (i.e. without coupling to the subsystem " $\mathrm{H}_{2} \mathrm{O}$ "). The general case will be discussed later in §5.4.2, where we learn that all internal EPs represent the large- $C_{T}$ limit of the " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ " system.

### 3.3 Ionization Fractions: Degree of Dissociation

### 3.3.1 Definition of $a_{j}$

The $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ comprises $N+1$ species denoted by $[j]$, where $j$ runs from 0 to $N$. Instead of the molar concentrations $[j]$ (which add up to the total amount $C_{T}$ ), it is convenient to use unitless ionization fractions $a_{0}, a_{1}$ to $a_{N}$ :

$$
\begin{equation*}
a_{j} \equiv \frac{[j]}{C_{T}} \quad \text { for } j=0,1,2, \ldots N \tag{3.57}
\end{equation*}
$$

They form the math skeleton of the subsystem "acid" with its typical dependence on $x($ or pH$)$ : $^{4}$

$$
\begin{equation*}
a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0} \quad \text { with } \quad a_{0}=\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right)^{-1} \tag{3.58}
\end{equation*}
$$

Merging the left and right equations yields:

$$
\begin{equation*}
a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0}=\frac{k_{j} / x^{j}}{\sum_{j=0}^{N} k_{j} / x^{j}} \quad \text { for } j=0,1,2, \ldots N \tag{3.59}
\end{equation*}
$$

The ionization fractions are solely functions of $x$ (or $\mathrm{pH}=-\lg x$ ); the only other ingredients are the cumulative equilibrium constants, introduced in (3.14):

$$
\begin{equation*}
k_{0}=1, k_{1}=K_{1}, k_{2}=K_{1} K_{2}, \ldots, k_{N}=K_{1} K_{2} \cdots K_{N} \tag{3.60}
\end{equation*}
$$

Due to the definition in (3.57), the ionization fractions are independent of the total concentration $C_{T}$, which is useful in graphical presentations, as shown in Fig 3.4. On the other hand, once we know $a_{j}$, the molar concentration of the acid species is obtained by multiplication with $C_{T}$ :

$$
\begin{equation*}
[j]=C_{T} a_{j}(x) \quad \text { for } j=0,1,2, \ldots N \tag{3.61}
\end{equation*}
$$

To make the pH dependence of $a_{j}$ more apparent, (3.59) can be written as

$$
\begin{equation*}
a_{j}(\mathrm{pH})=a_{0} k_{j} \cdot 10^{j \cdot \mathrm{pH}}=\frac{k_{j} 10^{j \cdot \mathrm{pH}}}{\sum_{j=0}^{N} k_{j} 10^{j \cdot \mathrm{pH}}} \tag{3.62}
\end{equation*}
$$

The ionization fractions are the building blocks of all relevant quantities that we will derive in the next chapters.

### 3.3.2 Bjerrum Plots \& Special Features of $a_{j}$

Bjerrum plots (dissociation diagrams) are a convenient way to visualize the pH dependence of the ionization fractions $a_{j}$. This is demonstrated in Fig 3.4 for four acids (based on pK values taken from Table 2.2).

[^6]

Figure 3.4: BJERRUM plots of ionization fractions for four acids (blue circles denote semi-EPs).

## Universality

Ionization fractions have the nice feature that they are independent of the acid's total amount $C_{T}$. Regardless of the assumed $C_{T}$ (either constant or pH -dependent), the shapes of the ionization-fractions remain the same - see examples in § 7.3 $\left(\mathrm{H}_{2} \mathrm{~A}\right.$ as titrant vs $\mathrm{H}_{2} \mathrm{~A}$ as analyte) and $\S 7.4$ (open vs closed $\mathrm{CO}_{2}$ system).

## Mass Balance

For any chosen value of $x($ or pH$)$ the sum of all ionization fractions equals 1 :

$$
\begin{equation*}
1=a_{0}+a_{1}+a_{2}+\cdots+a_{N}=\sum_{j=0}^{N} a_{j}(x) \quad(\text { for any } x \text { or } \mathrm{pH}) \tag{3.63}
\end{equation*}
$$

## Value Range

The ionization fractions are bound between 0 and 1 :

$$
\begin{equation*}
0<a_{j}<1 \quad(\text { for all } j) \tag{3.64}
\end{equation*}
$$

They never become negative or greater than 1. [Strictly speaking: The functions will come very close to the values 0 and 1 , but they never really reach them.]

## Equivalence Points

The equivalence points introduced in (3.44) and (3.45) can also be defined by equating two ionization fractions:

$$
\begin{array}{llll}
\operatorname{semi-EP}_{j}: & {[j-1]=[j]} & \Longleftrightarrow a_{j-1}=a_{j} & \Rightarrow x=K_{j} \\
\operatorname{EP}_{\mathrm{j}}: & {[j-1]=[j+1]} & \Longleftrightarrow a_{j-1}=a_{j+1} \quad \Rightarrow \quad x=\sqrt{K_{j} K_{j+1}} \tag{3.66}
\end{array}
$$

This applies only for the internal equivalence points:

|  | condition | range | pH | $n$ |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\operatorname{semi-~}^{\mathrm{EP}}{ }_{j}$ | $a_{j-1}=a_{j}$ | $j=1,2, \ldots N$ | $\mathrm{pK}_{\mathrm{j}}$ | $j-\frac{1}{2}$ | $(3.67)$ |
| $\mathrm{EP}_{\mathrm{j}}$ | $a_{j-1}=a_{j+1}$ | $j=1,2, \ldots N-1$ | $\mathrm{pH}_{\mathrm{j}}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right)$ | $j$ | $(3.68)$ |

Equivalence points are easily recognizable in the diagrams of Fig 3.4: The semi-EPs are located at the intersection of two adjacent ionization fractions, $a_{j-1}$ and $a_{j}$ (marked as blue circles); the EPs for integer $n$ are at intersections of ionization fractions $a_{j-1}$ and $a_{j+1}$ (marked as yellow circles). Notice that the latter are located at the maximum of $a_{j}$ (whose mathematical verification is given in (B.33) of Appendix B.3.2).

The actual values at the points of intersection are (cf. (B.35)):

$$
\begin{array}{lll}
\text { semi- } \mathrm{EP}_{\mathrm{j}} & a_{j}=a_{j-1} \simeq \frac{1}{2} & \left(\text { all other } a_{j} \simeq 0\right) \\
\mathrm{EP}_{\mathrm{j}} & a_{j}=1-2 a_{j-1} \simeq 1 & \left(\text { all other } a_{j} \simeq 0\right) \tag{3.70}
\end{array}
$$

### 3.3.3 Two Types of $a_{j}$ : S-Shaped vs Bell-Shaped

The acidity constants in the form of $\mathrm{pK}_{j}$ values subdivide the entire pH domain into $N+1$ distinct intervals, as shown in Fig 3.5. The $j^{\text {th }}$ interval is the subdomain in which the ionization fraction $a_{j}$ exercises its full dominance - see right diagrams in Fig 3.5. As indicated by colors, there are two types of curves: (i) S-shaped curves (sigmoid curves) in the 0 -th and the $N^{\text {th }}$ interval at the opposite ends of the pH scale (red color) and (ii) bell-shaped curves in all other intervals (blue color), with their maxima in the middle of the interval.

Note 1. For $N=1$, the red curves $a_{0}$ and $a_{1}$ bear a striking similarity to logistic functions or to the Fermi-Dirac distribution in statistical physics.

Note 2. The S-shaped curves appear as the two halves of a bell-shaped curve when the opposite ends are glued together at $\pm \infty$. ${ }^{5}$

Table 3.3 contrasts the two types of ionization fractions. Their otherness implies the distinction between external (outer) and internal (inner) equivalence points (cf. §3.2.2).

[^7]

Figure 3.5: Each ionization fraction $a_{j}$ has its own domain in the pH interval between two adjacent $\mathrm{pK}_{\mathrm{j}}$ values. ( HA - acetic acid, $\mathrm{H}_{2} \mathrm{~A}$ - carbonic acid, $\mathrm{H}_{3} \mathrm{~A}$ - phosphoric acid).

## Asymptotic Behavior

At the opposite ends of the pH scale, the two ionization fractions $a_{0}$ and $a_{N}$ attain the maximum value 1 :

$$
\begin{array}{lllll}
\text { strongly acidic: } & \mathrm{pH}<0 & (\text { or } x \rightarrow \infty) & a_{0}=1 & \text { all other } a_{j}=0 \\
\text { strongly alkaline: } & \mathrm{pH}>14 & (\text { or } x \rightarrow 0) & a_{N}=1 & \text { all other } a_{j}=0 \tag{3.72}
\end{array}
$$

This behavior is an important fact to identify them as cumulative distribution functions in [1]. [Note: The pH scale does not end at 0 or 14, but extends to $\mathrm{pH}<0$ and $\mathrm{pH}>14$ (in theory, even up to $-\infty$ and to $+\infty$ ).]

### 3.3.4 Two Types of Approximations

The formula for the ionization fractions in (3.58) can be approximated in two radically different ways:

- approximation 1: "piecewise $\log$-scale approximation" for $\lg a_{j}$
- approximation 2: "midpoint approximation" for $a_{j}$

Table 3.3: Two types of ionization fractions.

|  | Type 1 (S-shaped) | Type 2 (bell-shaped) |
| :--- | :--- | :--- |
| ionization fraction: | $a_{0}$ and $a_{n}$ | $a_{1}, a_{2}, \ldots a_{N-1}$ <br> (does not exist for 1-protic acids) |
| domain ( pH interval): | $\mathrm{pH}<\mathrm{pK}_{1}\left(\right.$ for $\left.a_{0}\right)$ <br> $\mathrm{pH}>\mathrm{pK}_{\mathrm{N}}\left(\right.$ for $\left.a_{N}\right)$ | $\mathrm{pK}_{\mathrm{j}}<\mathrm{pH}<\mathrm{pK}_{\mathrm{j}+1}$ |
| maximum at $\mathrm{pH}:$ | $-\infty\left(\right.$ for $\left.a_{0}\right)$ <br> $+\infty\left(\right.$ for $\left.a_{N}\right)$ | $\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right)$ |
| strongly acidic $(\mathrm{pH} \rightarrow 0):$ <br> strongly alkaline $(\mathrm{pH} \rightarrow 14):$ | $a_{0}=1, a_{N}=0$ <br> $a_{0}=0, a_{N}=1$ | $a_{j}=0$ |
| $a_{j}=0$ |  |  |

## Approximation 1

This approach focuses on the logarithm of $a_{j}$ (i.e., on $\lg a_{j}$ instead of $a_{j}$ itself). It is the approach that is used in textbooks as a graphical method for solving the algebraic equations of equilibrium systems (in double-logarithmic diagrams).

The approximate formula for $\lg a_{j}$ represents a sequence of linear function in pH :

$$
\begin{equation*}
\lg a_{j} \simeq(j-i) \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{\mathrm{j}}\right) \quad \text { for the } i^{\text {th }} \text { interval } \tag{3.73}
\end{equation*}
$$

where $\mathrm{pk}_{\mathrm{i}}=\mathrm{pK}_{1}+\mathrm{pK}_{2}+\ldots+\mathrm{pK}_{\mathrm{i}}$ and $\mathrm{pk}_{0}=0$. (For the derivation we refer to Appendix B.2.1) Note: In the special case of $j=i$ we get $\lg a_{j}=0$, that is $a_{j}=1$.

Figure 3.6: HÄGG's diagram: ionization fractions $\lg a_{j}$ for phosphoric acid based on the piecewise approximation in (3.73).

Fig 3.6 shows the approximation for phosphoric acid (as a triprotic acid). There are three pK values that subdivide the pH domain into four intervals. In each $i^{\text {th }}$
interval, $\lg a_{j}$ represents a straight line with integer-valued slope $(j-i)$ and offset $\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{\mathrm{j}}\right)$. For example, for $a_{2}$ (green dashed curve) we have:

$$
\lg a_{2} \simeq(2-i) \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{2}\right)
$$

with the following segments (straight lines) in the $i^{\text {th }}$ intervals:

$$
\begin{aligned}
& i=0: \quad(2-0) \mathrm{pH}+\left(0-\mathrm{pk}_{2}\right)=2 \mathrm{pH}-\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}\right)=2 \mathrm{pH}-9.35 \\
& i=1:(2-1) \mathrm{pH}+\left(\mathrm{pk}_{1}-\mathrm{pk}_{2}\right)=\mathrm{pH}-\mathrm{pK}_{2} \quad=\mathrm{pH}-7.21 \\
& i=2:(2-2) \mathrm{pH}+\left(\mathrm{pk}_{2}-\mathrm{pk}_{2}\right)=0 \quad=0 \\
& i=3:(2-3) \mathrm{pH}+\left(\mathrm{pk}_{3}-\mathrm{pk}_{2}\right)=-\mathrm{pH}+\mathrm{pK}_{3} \quad=-\mathrm{pH}+12.35
\end{aligned}
$$

## Approximation 2

This approach is based on the fact that the curves in Fig 3.4 look so elementary that one wonders whether these cannot be described by a much simpler formula. And this is indeed so; one can replace the exact formulas in (3.58) by simpler ones:

$$
\begin{align*}
a_{0} & \simeq\left(1+\frac{K_{1}}{x}\right)^{-1}  \tag{3.74}\\
a_{j} & \simeq\left(\frac{x}{K_{j}}+1+\frac{K_{j+1}}{x}\right)^{-1} \quad(\text { for } j=1 \text { to } N)  \tag{3.75}\\
a_{N} & \simeq\left(\frac{x}{K_{N}}+1\right)^{-1} \tag{3.76}
\end{align*}
$$

This approach relies on no more than two (adjacent) pK values; all other pK values are ignored. In fact, for diprotic acids it just coincides with the exact formula, ${ }^{6}$ but for $N$-protic acids with $N>2$ it deviates slightly. The small deviations from the exact description can only be recognized in logarithmic plots of $a_{j}$ - as shown for phosphoric acid $(N=3)$ in Fig 3.76.

Figure 3.7: HÄGG's diagram: ionization fractions for phosphoric acid. Solid lines exact description based on (3.58); dashed lines - approximations in (3.74) to (3.76).

[^8]
## Summary

The two approaches are complementary, as demonstrated in Fig 3.8 (for phosphoric acid). Approach 1 offers a very nice approximation in logarithmic plots, but fails to reproduce the S -shaped and bell-shaped curves in $\mathrm{pH}-a_{j}$ diagrams (dashed curves in bottom-left diagram). Conversely, Approach 2 reproduces the $a_{j}$ curves perfectly, but if we look more closely, we see deviations in the log-plots for values below $10^{-4}$ (dashed curves in the top-right diagram).

Figure 3.8: Ionization fractions for phosphoric acid in the two approximations (dashed lines). Solid lines: exact description based on (3.58).

### 3.4 Moments $Y_{L}$ : Weighted Sums over $a_{j}$

### 3.4.1 Definition of $Y_{L}$

The ionization fractions $a_{j}$ are the building blocks for the construction of so-called moments. The $L^{\text {th }} \tilde{m}$ oment $Y_{L}$ is defined as the weighting sum over $a_{j}$ :

$$
\begin{equation*}
Y_{L} \equiv \sum_{j=0}^{N} j^{L} a_{j} \tag{3.77}
\end{equation*}
$$

For $L=0$ it represents the mass conservation (because $0^{0}=1$ ):

$$
\begin{equation*}
Y_{0}=a_{0}+a_{1}+\cdots+a_{N} \quad(\text { for } L=0) \tag{3.78}
\end{equation*}
$$

For all other positive integers we have:

$$
\begin{equation*}
Y_{L}=a_{1}+2^{L} a_{2}+3^{L} a_{3} \cdots+N^{L} a_{N} \quad(\text { for } L \geq 1) \tag{3.79}
\end{equation*}
$$

As indicated in Fig 3.9, the moments itself are the building blocks of a whole series of relevant quantities: $Y_{0}$ represents the mass balance; $Y_{1}$ will turn out to be the key quantity in the description of acid-base titration curves in $\S 5.3 ; Y_{2}$ and $Y_{3}$ will enter the buffer intensity and its derivative in $\S 6.2$ (cf. equations (6.19) and (6.20) on page 61).

$$
\begin{aligned}
& \begin{array}{l}
\text { moments } Y_{L} \\
\text { (sums over } \left.a_{j}\right)
\end{array} \quad Y_{L} \equiv \sum_{j=0}^{N} j^{\mathrm{L}} a_{\uparrow}(x) \\
& \text { ionization fractions } \\
& Y_{0}=a_{0}+a_{1}+\ldots+a_{N}=1 \Rightarrow \text { mass balance } \\
& Y_{1}=a_{1}+2 a_{2}+\ldots+N a_{N} \Rightarrow \text { titration function } \\
& Y_{2}=a_{1}+4 a_{2}+\ldots+N^{2} a_{N} \Rightarrow \text { buffer intensity } \beta \\
& Y_{3}=a_{1}+8 a_{2}+\ldots+N^{3} a_{N} \Rightarrow 1^{\text {st }} \text { derivative of } \beta
\end{aligned}
$$

Figure 3.9: Moments $Y_{L}$ as building blocks for relevant quantities that will be introduced in equations (6.18) to (6.20) on page 61 .

The moments $Y_{L}$ are non-negative functions, living in the range $0<Y_{L} \leq N^{L}$ (whereby the equals sign only applies to $Y_{0}$, all other $Y_{L}$ approach the upper limit of $N^{L}$ asymptotically).

Fig 3.10 illustrates how the "titration curve" $Y_{1}$ emerges from the set of (three) ionization fractions $a_{j}$ (for phosphoric acid as a triprotic acid).

Fig 3.11 displays the pH dependence of $Y_{1}$ to $Y_{4}$ for four acids (with pK values taken from Table 2.2). Note that for monoprotic acids (top-left diagram) all moments are equal, i.e. the four $Y_{L}$-curves cover each other.

## pH Dependence

The moments, just like the ionization fractions, are solely functions of $x$ (or pH $=-\lg x$ ); the only other ingredients are the (cumulative) equilibrium constants of the acid. From (3.59) we obtain: ${ }^{7}$

$$
\begin{equation*}
Y_{1}(x)=\frac{\sum_{j=0}^{N} j \cdot\left(k_{j} / x^{j}\right)}{\sum_{j=0}^{N}\left(k_{j} / x^{j}\right)}=\frac{\sum_{j=0}^{N} j \cdot k_{j} x^{N-j}}{\sum_{j=0}^{N} k_{j} x^{N-j}} \tag{3.80}
\end{equation*}
$$

Converting $x$ to pH yields:

$$
\begin{equation*}
Y_{1}(\mathrm{pH})=\frac{\sum_{j=0}^{N} j \cdot k_{j} 10^{j \cdot \mathrm{pH}}}{\sum_{j=0}^{N} k_{j} 10^{j \cdot \mathrm{pH}}} \tag{3.81}
\end{equation*}
$$

[^9]
## Figure 3.10:

Construction of $Y_{1}$ (blue curve in bottom diagram) from summation over three weighted ionization fraction $a_{j}$. (Example: phosphoric acid as a triprotic acid).

### 3.4.2 Moments and EPs

## Internal EPs

For the equivalence points, the following simple relationships are obtained (see (B.26) and (B.27) in Appendix B.3.1):

$$
\begin{array}{lll}
\text { semi- } \mathrm{EP}_{\mathrm{j}}: \quad \mathrm{pK} \\
\mathrm{j} & a_{j}=a_{j-1} \simeq \frac{1}{2} & Y_{L}=\frac{1}{2}\left\{(j-1)^{L}+j^{L}\right\}  \tag{3.83}\\
\mathrm{EP}_{\mathrm{j}}: \mathrm{pH} & =\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right) & a_{j}=1-2 a_{j-1} \simeq 1
\end{array} Y_{L} \simeq j^{L} .
$$

This is valid only for the so-called internal equivalence points ( $j=1$ to $N-1$ ), and for $L \geq 1$. From these expressions the following special values are obtained:

$$
\begin{array}{ll}
Y_{L} \text { at semi- } \mathrm{EP}_{\mathrm{j}}: & Y_{L} \text { at } \mathrm{EP}_{\mathrm{j}}: \\
Y_{L}\left(\mathrm{pK}_{1}\right)=\frac{1}{2} & Y_{L}\left(\mathrm{pH}_{1}\right)=1 \\
Y_{L}\left(\mathrm{pK}_{2}\right)=\frac{1}{2}\left(1+2^{L}\right) & Y_{L}\left(\mathrm{pH}_{2}\right)=2^{L} \\
Y_{L}\left(\mathrm{pK}_{3}\right)=\frac{1}{2}\left(2^{L}+3^{L}\right) & Y_{L}\left(\mathrm{pH}_{3}\right)=3^{L} \\
Y_{1}\left(\mathrm{pK}_{\mathrm{j}}\right)=j-\frac{1}{2} & Y_{1}\left(\mathrm{pH}_{\mathrm{j}}\right)=j \\
Y_{2}\left(\mathrm{pK}_{\mathrm{j}}\right)=(j-1) j+\frac{1}{2} & Y_{2}\left(\mathrm{pH}_{\mathrm{j}}\right)=j^{2}
\end{array}
$$

The two relations in (3.87) can be combined into the remarkable formula valid for all internal EPs and semi-EPs to a very good approximation (though not exactly):

$$
\begin{equation*}
Y_{1}\left(\mathrm{pH}_{\mathrm{n}}\right)-n=0 \quad \text { for } n=\frac{1}{2}, 1, \ldots, N-\frac{1}{2} \tag{3.89}
\end{equation*}
$$

Figure 3.11: pH dependence of $Y_{1}$ to $Y_{4}$ for four acids. In the case of monoprotic acids (top-left diagram) all $Y_{L}$ are equal; the four curves lie on top of each other.

In fact, it establishes the link between $\mathrm{EP}_{\mathrm{n}}$ and $\mathrm{pH}_{\mathrm{n}}$ defined in (3.51). A graphical representation is provided by the small circles in Fig 3.12.

Figure 3.12:
Moment $Y_{1}(\mathrm{pH})$ for phosphoric acid. The small circles (dots) indicate the relationship in (3.89).

## External EPs (Asymptotic Behavior)

The asymptotic behavior results from (3.71) and (3.72):

$$
\begin{array}{lll}
Y_{L}(\mathrm{pH} \rightarrow 0)=0 & \text { or } & Y_{L}(x \rightarrow \infty)=0 \\
Y_{L}(\mathrm{pH} \rightarrow 14)=N^{L} & \text { or } & Y_{L}(x \rightarrow 0)=N^{L} \tag{3.91}
\end{array}
$$

In particular, for $Y_{1}$ we get the asymptotic values 0 and 3 at the opposite ends of the pH scale, as shown Fig 3.12. These values correspond to the two external $\mathrm{EPs}\left(\mathrm{EP}_{0}\right.$ and $\left.\mathrm{EP}_{3}\right)$. In this case, (3.89) seems to be applicable even to external EPs defined by the indices $n=0$ and $n=N$.

No one regards what is at his feet; we all gaze at the stars.

- Quintus Ennius, 239-169 BC

## 2-Component System: " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ "

## Contents

4.1 Basic Set of Equations ..... 37
4.2 Closed-Form Equations ..... 38

### 4.1 Basic Set of Equations

In this Chapter we consider the coupled system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ ". The basic set of $N+3$ equations, given in (2.32) to (2.37), becomes (after replacing the acid species [ $j]$ by the ionization fractions $\left.a_{j}=[j] / C_{T}\right)$ :

$$
\begin{array}{llrl}
K_{w} & =x(x+w) & & \text { (subsystem } \left.\mathrm{H}_{2} \mathrm{O}\right) \\
k_{1} & =x\left(a_{1} / a_{0}\right) & \text { or } a_{1}=\left(k_{1} / x\right) a_{0} & \left(\mathrm{H}_{\mathrm{N}} \mathrm{~A}: 1^{\text {st }}\right. \text { diss step) } \\
k_{2} & =x\left(a_{2} / a_{0}\right) \quad \text { or } a_{2}=\left(k_{2} / x^{2}\right) a_{0} & \left(\mathrm{H}_{N} \mathrm{~A}: 2^{\text {nd }}\right. \text { diss step) } \\
\vdots & & \\
k_{N} & =x\left(a_{N} / a_{0}\right) \text { or } a_{N}=\left(k_{N} / x^{N}\right) a_{0} & \left(\mathrm{H}_{\mathrm{N}} \mathrm{~A}: N^{\text {th }}\right. \text { diss step) } \\
1 & =a_{0}+a_{1}+a_{2}+\cdots+a_{N} & \left(\mathrm{H}_{N} \mathrm{~A}: \text { mass balance }\right) \\
0 & =\left(a_{1}+2 a_{2}+\cdots+N a_{N}\right)+w / C_{T}=Y_{1}+\frac{w}{C_{T}} & \text { (charge bal.) }
\end{array}
$$

## Subsystem $\mathbf{H}_{2} \mathbf{O}$

The subsystem $\mathrm{H}_{2} \mathrm{O}$ with its two components $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$is expressed by $x=\left\{\mathrm{H}^{+}\right\}$ and $w(x)$. The latter includes the self-ionization of water controlled by $K_{w}$ :

$$
\begin{equation*}
w=\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \simeq \frac{K_{w}}{x}-x \tag{4.7}
\end{equation*}
$$

## Subsystem $\mathbf{H}_{\mathbf{N}} \mathbf{A}$

The 1-component system "acid" $\left(\mathrm{H}_{\mathrm{N}} \mathrm{A}\right)$ was introduced and discussed in Chapter 3. The $N$-protic acid comprises $N+1$ acid species $[j]$, which are described by the subset of $N+1$ equations (4.2) to (4.5).

Coupling: $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$
Both subsystems are linked together by the charge-balance equation (4.6). The schema in Fig 4.1 (for an $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ ) is a generalization of Fig 2.5 (for the diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ ).

Figure 4.1: The two subsystems " $\mathrm{H}_{2} \mathrm{O}$ " and " $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ " are coupled via the charge-balance equation.

### 4.2 Closed-Form Equations

### 4.2.1 Forward and Inverse Task

The 2-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ " is controlled by two "master variables": pH and the amount of acid $C_{T}$, but only one of them can be freely chosen. Hence, two tasks emerge:
$\left.\begin{array}{l}\text { - given } \mathrm{pH} \Rightarrow \\ \text { - given } C_{T} \Rightarrow \\ \text { calculate } C_{T} \\ \text { calculate } \mathrm{pH}\end{array}\right\} \quad$ and equilibrium speciation $[j]=C_{T} a_{j}$
Forward Task: $C_{T}=C_{T}(\mathbf{p H})$
For a given pH (or $x=10^{-\mathrm{pH}}$ ), $C_{T}$ and the composition of the equilibrium system is obtained as follows:

$$
\begin{align*}
\mathrm{pH}(\text { or } x) & \Rightarrow \text { amount of acid: } C_{T}(x)=-\frac{w}{Y_{1}} \quad \text { with } Y_{1}=\sum_{j=0}^{N} j a_{j}(x)  \tag{4.8}\\
& \Rightarrow \text { speciation }(0 \leq j \leq N): \quad[j]=C_{T}(x) a_{j}(x)=\left(-\frac{w}{Y_{1}}\right) a_{j}(x) \tag{4.9}
\end{align*}
$$

Eq (4.8) represents an explicit function:

$$
\begin{equation*}
C_{T}=f(\mathrm{pH}) \tag{4.10}
\end{equation*}
$$

This dependence is displayed in the left diagram of Fig 4.2. [Note: Exactly the same functions represent the pH dependence of the equivalence points $\mathrm{EP}_{0}$ plotted as blue curves in the diagrams of Fig 5.10 on page 53.]

Figure 4.2: Functional relationship between pH and the amount of acid $C_{T}$. The left diagram is based on (4.8); right diagram: same as left diagram, only axes interchanged.

## Inverse Task: $\mathbf{p H}=\mathbf{p H}\left(C_{T}\right)$

The inverse task to calculate the pH (or $x$ ) for a given $C_{T}$ is intricate because an explicit function, such as $\mathrm{pH}=f\left(C_{T}\right)$, does not exist for $N>1$. The only thing we can offer is an implicit function in the form of a polynomial ${ }^{1}$ of degree $N+2$ :

$$
\begin{equation*}
0=\sum_{j=0}^{N}\left\{x^{2}-j C_{T} x-K_{w}\right\} k_{j} x^{N-j} \tag{4.11}
\end{equation*}
$$

Compared to the polynomial for the 1-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ " in (3.30), this polynomial is two degrees higher ( $N+2$ rather than $N$ ), which makes the solution more difficult. In principle, there is no algebraic expression for solving polynomials with a degree higher than 4 , no matter how hard we try. Thus, numerical rootfinding methods should be applied. The curves in the right diagram of Fig 4.2 were plotted by a trick: Take the left diagram and interchange the axes.

Note. What is called here "forward task" and what is called "inverse task" is arbitrary. In this case we call "forward task" the simpler calculation method.

### 4.2.2 Examples

Example $N=1 \quad \Longrightarrow \quad$ Cubic Equation
The monoprotic acid represents the simplest case, where the sum in (4.11) runs over two terms only, $j=0$ and 1 . With $k_{0}=1$ and $k_{1}=K_{1}$ we get a cubic equation:

$$
\begin{equation*}
0=x^{3}+K_{1} x^{2}-\left(C_{T} K_{1}+K_{w}\right) x-K_{1} K_{w} \tag{4.12}
\end{equation*}
$$

[^10]
## Example $N=2 \Longrightarrow$ Quartic Equation

For a diprotic acid, we get from (4.11) with $k_{0}=1, k_{1}=K_{1}$, and $k_{2}=K_{1} K_{2}$ a quartic equation:

$$
\begin{equation*}
0=x^{4}+K_{1} x^{3}+\left(K_{1} K_{2}-C_{T} K_{1}-K_{w}\right) x^{2}-K_{1}\left(2 C_{T} K_{2}+K_{w}\right) x-K_{1} K_{2} K_{w} \tag{4.13}
\end{equation*}
$$

This equation can be found in textbooks, e.g. [2]. If you set $K_{2}=0$, you arrive at (4.12).

The greatest, and most robust, contribution to knowledge consists in removing what we think is wrong.

### 5.1 Introduction

### 5.1.1 Definitions

The previous Chapter provided the algebraic description of the 2-component system " $\mathrm{H}_{\mathrm{N}} \mathrm{A}+\mathrm{H}_{2} \mathrm{O}$ " (polyprotic acid in water). Starting from the set of equations (2.32) to (2.37) we arrived at an analytical formula in (4.9) which predicts the amount of $C_{T}$ for a given pH and vice versa.

A new degree of freedom comes into play when a strong base (or strong acid) is added to this "undisturbed" system: the 2-component system becomes a 3component system. The term "strong" means complete dissociation in water:

$$
\begin{array}{ll}
\text { strong mono-acidic base: } & \mathrm{BOH}=\mathrm{B}^{+}+\mathrm{OH}^{-} \\
\text {strong mono-protic acid: } & \mathrm{HA}=\mathrm{H}^{+}+\mathrm{A}^{-} \tag{5.2}
\end{array}
$$

Here the Arrhenius base BOH stands for NaOH or KOH (i.e. $\mathrm{B}^{+}=\mathrm{Na}^{+}$or $\mathrm{K}^{+}$) while HX represents $\mathrm{HCl}, \mathrm{HI}$, or HBr (i.e. $\mathrm{X}^{-}=\mathrm{Cl}^{-}, \mathrm{I}^{-}$, or $\mathrm{Br}^{-}$).

The addition of a strong base or a strong acid (to the weak acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ ) is known as:

$$
\begin{array}{llll}
\text { alkalimetric titration: } & \mathrm{H}_{\mathrm{N}} \mathrm{~A}+\mathrm{BOH} & \Longrightarrow & \mathrm{pH} \text { increases } \\
\text { acidimetric titration: } & \mathrm{H}_{\mathrm{N}} \mathrm{~A}+\mathrm{HX} & \Longrightarrow & \mathrm{pH} \text { decreases } \tag{5.4}
\end{array}
$$

$C_{B}$ and $C_{A}$ denote the amounts of strong base and strong acid. They can be related to the total amount of $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ by

$$
\begin{equation*}
n_{B}=\frac{C_{B}}{C_{T}} \quad \text { and } \quad n_{A}=\frac{C_{A}}{C_{T}} \tag{5.5}
\end{equation*}
$$

Since the strong base and strong acid act in opposing directions (both cancel each other out), we combine the two equations into one

$$
\begin{equation*}
\text { equivalent fraction: } n=\frac{C_{B}-C_{A}}{C_{T}} \tag{5.6}
\end{equation*}
$$

where either $C_{B}$ or $C_{A}$ is zero. In this way, the equivalent fraction $n$ of the titrant is positive for the alkalimetric titration and negative for the acidimetric titration. ${ }^{1}$ Note that $n=0$ represents the "undisturbed" system.

## Example

Fig 5.1 provides the acid-base titration of the carbonate system with $C_{T}=10 \mathrm{mM}$ $\mathrm{H}_{2} \mathrm{CO}_{3}$. The pure $\mathrm{H}_{2} \mathrm{CO}_{3}$ system is characterized by $\mathrm{pH}=4.17$ (at $n=0$ ). Larger pH values are obtained through the addition of NaOH ( $n$ is positive); lower pH values through the addition of HCl ( $n$ is negative). The small circles at the three integer values $n=0,1$, and 2 indicate the equivalence points $\mathrm{EP}_{0}, \mathrm{EP}_{1}$, and $\mathrm{EP}_{2}$.

Figure 5.1: Titration curve $\mathrm{pH}=\mathrm{pH}(n)$ of the carbonate system ( $10 \mathrm{mM} \mathrm{H} \mathrm{H}_{2} \mathrm{CO}_{3}$ ).

The same titration curve as in Fig 5.1 (valid for $C_{T}=10 \mathrm{mM}$ ) is shown in Fig 5.2 together with two additional curves for $C_{T}=1 \mathrm{mM}$ and 100 mM . The only difference between the left and right diagrams in Fig 5.2 is that the $x$ - and $y$-axes are swapped. [The curves are calculated using (5.32) on page 46.]

### 5.1.2 Special Case: Diprotic Acid

Given is a diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ with amount $C_{T}$ to which a strong base BOH (with $\mathrm{B}^{+}=\mathrm{Na}^{+}$or $\mathrm{K}^{+}$) is added:

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{~A}+\mathrm{nBOH}=\mathrm{B}_{\mathrm{n}} \mathrm{H}_{2-\mathrm{n}} \mathrm{~A}+\mathrm{nH}_{2} \mathrm{O} \tag{5.7}
\end{equation*}
$$

[^11]

Figure 5.2: Titration curves of the carbonate system (for 1, 10 , and $100 \mathrm{mM} \mathrm{H} \mathrm{H}_{2} \mathrm{CO}_{3}$ ). Left diagram: $n=n(\mathrm{pH})$, right diagram: $\mathrm{pH}=\mathrm{pH}(n)$.

Here $n$ acts as a stoichiometric coefficient that embodies the ratio of the added strong base to the amount of the diprotic acid: $n=C_{B} / C_{T}$ as introduced in (5.5) and (5.6).

The entity $\mathrm{B}_{\mathrm{n}} \mathrm{H}_{2-\mathrm{n}} \mathrm{A}$ in the reaction formula (5.7) does not survive in water; it dissociates into several aqueous species - as indicated in Fig 5.3.

Figure 5.3: Alkalimetric titration of a diprotic acid with a strong base.

The variation of $n$ (or $C_{B}$ ) in the reaction formula (5.7) by adding a strong base is called alkalimetric titration. Because strong bases dissociate completely, we have:

$$
\begin{equation*}
C_{B} \equiv[\mathrm{BOH}]_{\mathrm{T}}=\mathrm{B}^{+} \quad \text { (strong base) } \tag{5.8}
\end{equation*}
$$

The special cases $n=0,1$, and 2 are of particular interest. When these three integers are inserted into the reaction formula (5.7), the entity $\mathrm{B}_{\mathrm{n}} \mathrm{H}_{2-\mathrm{n}} \mathrm{A}$ becomes a pure acid, an ampholyte and a (conjugate) base:

$$
\begin{array}{llll}
n=0: & \text { pure } \mathrm{H}_{2} \mathrm{~A} \text { solution } & (\text { acid }) & \Longleftrightarrow \mathrm{H}_{2} \mathrm{~A} \mathrm{EP} \\
n=1: & \text { pure } \mathrm{BHA} \text { solution } & \text { (ampholyte) } & \Longleftrightarrow \mathrm{HA}^{-} \mathrm{EP} \\
n=2: & \text { pure } \mathrm{B}_{2} \mathrm{~A} \text { solution } & \text { (base) } & \Longleftrightarrow \mathrm{A}^{-2} \mathrm{EP} \tag{5.11}
\end{array}
$$

In fact, $n=0,1$, and 2 define the three equivalence points $\left(\mathrm{EP}_{0}, \mathrm{EP}_{1}, \mathrm{EP}_{2}\right)$ of a diprotic acid - introduced in § 3.2.1 and discussed in § 7.2 below. [Example: For " $\mathrm{H}_{2} \mathrm{CO}_{3}$ plus NaOH " we obtain pure solutions of $\mathrm{H}_{2} \mathrm{CO}_{3}, \mathrm{NaHCO}_{3}$ and $\mathrm{Na}_{2} \mathrm{CO}_{3}$.]

## Charge Balance

The principle of electro-neutrality requires that a solution must contain equal numbers of anions and cations:

$$
\begin{equation*}
\left[\mathrm{H}^{+}\right]+\left[\mathrm{B}^{+}\right]=\left[\mathrm{HA}^{-}\right]+2\left[\mathrm{~A}^{-2}\right]+\left[\mathrm{OH}^{-}\right] \tag{5.12}
\end{equation*}
$$

Replacing $\left[\mathrm{B}^{+}\right]$by $C_{B}$, as stated in (5.8), we get

$$
\begin{equation*}
C_{B}=\left[\mathrm{HA}^{-}\right]+2\left[\mathrm{~A}^{-2}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \tag{5.13}
\end{equation*}
$$

## Base Equations

The set of algebraic equations to describe the alkalimetric titration of a diprotic acid by a strong base generalizes the equations (2.21) to (2.25) introduced in § 2.2.1:

$$
\begin{array}{rll}
K_{w} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{OH}^{-}\right\} & \\
K_{1} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{HA}^{-}\right\} /\left\{\mathrm{H}_{2} \mathrm{~A}\right\} & \\
K_{2} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{A}^{-2}\right\} /\left\{\mathrm{HA}^{-}\right\} & \\
C^{\text {st }} \text { diss step } & \\
C_{T} & =\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right]+\left[\mathrm{A}^{-2}\right] &  \tag{5.18}\\
C_{B} & =\left[\mathrm{HA}^{-}\right]+2\left[\mathrm{~A}^{-2}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] & \\
\text {(chass step balance }) \\
\left.\mathrm{H}_{2} \mathrm{O}\right) \\
\text { (chalance) }
\end{array}
$$

It differs from the original set by the last equation only, which is the charge balance taken from (5.13). In fact, it is the sole equation into which the "strong base" creeps into this set of equations; the other four equations in this set are completely unrelated to $C_{B}$. For $C_{B}=0$ the set reduces to the description of the base-free diprotic-acid system.

## Proton Balance

In textbooks, (5.18) is sometimes introduced through the concept of "proton balance" - a special topic which is explained in Appendix C. For diprotic acids the proton balance yields:

$$
\begin{equation*}
0=\left[\mathrm{H}^{+}\right]+\mathrm{n}\left[\mathrm{H}_{2} \mathrm{~A}\right]+(\mathrm{n}-1)\left[\mathrm{HA}^{-}\right]+(\mathrm{n}-2)\left[\mathrm{A}^{-2}\right]-\left[\mathrm{OH}^{-}\right] \tag{5.19}
\end{equation*}
$$

Using $n=C_{B} / C_{T}$ and $C_{T}=\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right]+\left[\mathrm{A}^{-2}\right]$, this formula converts to (5.18).

### 5.2 Basic Set of Equations

### 5.2.1 The 3-Component System

The acid-base system is made up of three components:

- pure water $\}$ the "base-free" or "undisturbed" system
- weak $N$-protic acid $\left.\mathrm{H}_{\mathrm{N}} \mathrm{A}\right\}$ of Chapter 4
- strong mono-acidic base BOH

It is characterized by

$$
N+4 \text { species (variables): } \overbrace{\mathrm{H}^{+}, \mathrm{OH}^{-}, \underbrace{\mathrm{H}_{\mathrm{N}} \mathrm{~A}, \mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}, \ldots, \mathrm{A}^{-\mathrm{N}}}_{N+1 \text { acid species }}}^{\text {"undisturbed system" }}, \mathrm{B}^{+}
$$

Instead of $\left[\mathrm{B}^{+}\right]$we use the parameter $n=C_{B} / C_{T}$. The description of acid-base titrations is then built on a set of $N+3$ nonlinear equations:

$$
\begin{array}{rlrl}
K_{w} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{OH}^{-}\right\} & & \text {(self-ionization of } \left.\mathrm{H}_{2} \mathrm{O}\right) \\
K_{1} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right\} /\left\{\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right\} & & \left(1^{\text {st }} \text { diss step }\right) \\
K_{2} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right\} /\left\{\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right\} & & \left(2^{\text {nd }} \text { diss step }\right) \\
\vdots & & \\
K_{N} & =\left\{\mathrm{H}^{+}\right\} \cdot\left\{\mathrm{A}^{-\mathrm{N}}\right\} /\left\{\mathrm{HA}^{-(\mathrm{N}-1)}\right\} & & \left(\mathrm{N}^{\text {th }} \text { diss step }\right) \\
C_{T} & =\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]+\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+\ldots+\left[\mathrm{A}^{-\mathrm{N}}\right] & & (\text { mass balance }) \\
C_{B} & =\left[\mathrm{H}_{\mathrm{N}-1} \mathrm{~A}^{-}\right]+2\left[\mathrm{H}_{\mathrm{N}-2} \mathrm{~A}^{-2}\right]+\ldots+N\left[\mathrm{~A}^{-\mathrm{N}}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \tag{5.25}
\end{array}
$$

This set of equations is an extension of the diprotic-acid case in (5.14) to (5.18) from $N=2$ to any large $N$. This is also an extension of the "undisturbed $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ system" defined by the set of $N+3$ equations (2.26) to (2.31). The latter is re-established when $C_{B}$ is set to zero (in the last equation). In fact, the only difference to the original set of equations (2.26) to (2.31) is just the charge-balance equation in the last line.

Since we have $N+4$ variables, but only $N+3$ equations, the description is given one degree of freedom: We can vary the parameter $n$ to change the pH (for a fixed value of $C_{T}$ ).

Two assumptions are necessary to derive closed-form expressions (one-line formulas) from the set of equations (5.21) to (5.25):

- activities should be replaced by concentrations: $\{\cdot\} \rightarrow[\cdot]$
- the strong base BOH dissolves completely without forming aqueous species (such as $\mathrm{NaCO}_{3}^{-}$or $\mathrm{NaHCO}_{3}(\mathrm{aq})$ )

The first assumption is fulfilled either in dilute systems or by switching to conditional equilibrium constants ${ }^{c} K$ introduced in (2.7). These are so-called "ideal conditions"; counterexamples for "real conditions" will be given in § 7.6.

### 5.2.2 Closed-Form Expressions

The procedure for solving the set of algebraic equations (5.21) to (5.25) is the same as that we used in previous paragraphs (cf. in § 4.2):

- replace activities by concentrations: $\{\cdot\} \rightarrow[\cdot]$ in (5.21) to (5.23)
- replace acid species $[j]$ by ionization fractions $a_{j}$ in (5.21) to (5.25)
- replace $\left\{\mathrm{H}^{+}\right\}$by $x$ and $\left[\mathrm{OH}^{-}\right]$by $K_{w} / x-x$, and use $w(x)$ defined in (4.7)
- use the compact notation $Y_{1}$ for the sums over $a_{j}$ in (5.25)

In this way, the set of $N+3$ equations simplifies to:

$$
\begin{array}{rlrr}
K_{w} & =x(x+w) & & \left(\text { (subsystem } \mathrm{H}_{2} \mathrm{O}\right) \\
k_{1} & =x\left(a_{1} / a_{0}\right) & \text { or } a_{1}=\left(k_{1} / x\right) a_{0} & \left(\mathrm{H}_{N} \mathrm{~A}: 1^{\text {st }}\right. \text { diss step) } \\
k_{2} & =x\left(a_{2} / a_{0}\right) \quad \text { or } a_{2}=\left(k_{2} / x^{2}\right) a_{0} & \left(\mathrm{H}_{\mathrm{N}} \mathrm{~A}: 2^{\text {nd }}\right. \text { diss step) } \\
\vdots & & \\
k_{N} & =x\left(a_{N} / a_{0}\right) \quad \text { or } a_{N}=\left(k_{N} / x^{N}\right) a_{0} & \left(\mathrm{H}_{\mathrm{N}} \mathrm{~A}: N^{\text {th }}\right. \text { diss step) } \\
1 & =a_{0}+a_{1}+a_{2}+\cdots+a_{N} & \left(\mathrm{H}_{N} \mathrm{~A}:\right. \text { mass balance) }  \tag{5.31}\\
n & =Y_{1}+w / C_{T} & \text { (charge balance) }
\end{array}
$$

This set of equations upgrades (4.1) to (4.6) from an acid system to an acid-base system with the parameter $n$ as the new ingredient.

The essence of the entire set of equations is contained in the closed-form expression (taken from the last line):

$$
\begin{equation*}
n(x)=Y_{1}(x)+\frac{w(x)}{C_{T}} \tag{5.32}
\end{equation*}
$$

The information contained in all other equations - i.e. equations (5.26) to (5.30) - is encapsulated in the definition of $Y_{1}$ and $w$ :

$$
\begin{align*}
Y_{L} & =\sum_{j=0}^{N} j \cdot a_{j}=a_{1}+2 a_{2}+3 a_{3}+\cdots+N a_{N}  \tag{5.33}\\
w & =\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right] \simeq \frac{K_{w}}{x}-x \tag{5.34}
\end{align*}
$$

In (5.32), each of the three terms represents one of the three components (subsystems): $n$ - the strong base, $w / C_{T}$ - the water, and $Y_{1}$ - the acid. This is summarized in Fig 5.4, which illustrates how the three components "pure $\mathrm{H}_{2} \mathrm{O}$ ", " $N$-protic acid", and "strong base" are coupled via one single equation: the chargebalance equation.

Figure 5.4: The acid-base system: The three components

### 5.2.3 Polynomials for $x=10^{-\mathrm{pH}}$

Eq (5.32) can be solved for $x$ (or pH ). This is done in Appendix B.1.2 with the final result in (B.8), which is a polynomial of degree $N+2$ in $x$ :

$$
\begin{equation*}
0=\sum_{j=0}^{N}\left\{x^{2}+(n-j) C_{T} x-K_{w}\right\} k_{j} x^{N-j} \tag{5.35}
\end{equation*}
$$

For $n=0$ it falls back to (4.11) on page 39. Theoretically, this equation can be used to calculate $x$, but in practice it's a difficult task, even for a cubic equation. For higher-order polynomials, numerical root-finding methods should be used.

Example $N=1$
The monoprotic acid represents the simplest case, where the sum in (5.35) runs over two terms only, $j=0$ and 1 . With $k_{0}=1$ and $k_{1}=K_{1}$ we get a cubic equation, i.e. a polynomial of degree 3 in $x\left(=10^{-\mathrm{pH}}\right)$ :

$$
\begin{equation*}
0=x^{3}+\left\{K_{1}+n C_{T}\right\} x^{2}+\left\{(n-1) C_{T} K_{1}-K_{w}\right\} x-K_{1} K_{w} \tag{5.36}
\end{equation*}
$$

which generalizes (4.12) for $n \neq 0$. It predicts $x$ (or pH ) for any given pair of $C_{T}$ and $n$. Alternatively, replacing $n$ by $C_{B}=n C_{T}$ yields:

$$
\begin{equation*}
0=x^{3}+\left\{K_{1}+C_{B}\right\} x^{2}+\left\{\left(C_{B}-C_{T}\right) K_{1}-K_{w}\right\} x-K_{1} K_{w} \tag{5.37}
\end{equation*}
$$

Example $N=2$
For a diprotic acid, we get from (5.35) with $k_{0}=1, k_{1}=K_{1}$, and $k_{2}=K_{1} K_{2}$ a quartic equation:

$$
\begin{array}{r}
0=x^{4}+\left\{K_{1}+n C_{T}\right\} x^{3}+\left\{K_{1} K_{2}-(n-1) C_{T} K_{1}-K_{w}\right\} x^{2} \\
+K_{1}\left\{(n-2) C_{T} K_{2}+K_{w}\right\} x-K_{1} K_{2} K_{w} \tag{5.38}
\end{array}
$$

which generalizes (4.13) for $n \neq 0$. It predicts $x$ (or pH ) for any given pair of $C_{T}$ and $n$. Replacing $n$ by $C_{B}=n C_{T}$ yields:

$$
\begin{align*}
0=x^{4}+\left\{K_{1}+\right. & \left.C_{B}\right\} x^{3}+\left\{K_{1} K_{2}-\left(C_{B}-C_{T}\right) K_{1}-K_{w}\right\} x^{2} \\
& +K_{1}\left\{\left(C_{B}-2 C_{T}\right) K_{2}+K_{w}\right\} x-K_{1} K_{2} K_{w} \tag{5.39}
\end{align*}
$$

Setting $K_{2}=0$, we arrive at (5.36) and (5.37). As will be shown later in § 8.1, in the case of strong acids all polynomials simplify (their degree decreases by one unit).

## Summary

Either the closed-form expression in (5.32) or the polynomial in (5.35) are selfsufficient ways to describe the acid-base titration completely. Both are different encodings of one and the same thing, namely the set of $N+3$ equations (5.26) to (5.31).

Figure 5.5: The analytical solution in (5.32) is constructed from acidity constants and ionization fractions.

### 5.2.4 Lego-Set of Building Blocks

The analytical solution in (5.32) can be constructed "Lego-like" from building blocks of increasing complexity (acidity constants $K_{j}$, ionization fractions $a_{j}$, moments $Y_{L}$ ). The hierarchy is sketched in Fig 5.5.

At the lowest level there are the $N$ acidity constants $K_{1}$ to $K_{N}$ (as irreducible essence of acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ ), which - after multiplication - form cumulative equilibrium constants $k_{1}$ to $k_{N}$. These constants, in combination with the variable $x=\left\{\mathrm{H}^{+}\right\}$, enter the ionization fractions $a_{j}$ (which embody the law of mass action in each dissociation step). Then, the ionization fractions are summed up to form the moment $Y_{1}$ as the central part of the final equation. The only other ingredient is the quantity $w(x)=K_{w} / x-x$ describing the self-ionization of water.

The usefulness of the higher moments $Y_{L}$ (i.e. for $L \geq 2$ ) becomes clear later on, when the moments are used as building blocks for other key quantities:

- $Y_{0} \Rightarrow$ mass balance

$$
\left(Y_{0}=1\right)
$$

- $Y_{1} \Rightarrow$ enters buffer capacity $n(x) \quad$ in (5.32)
- $Y_{2} \Rightarrow$ enters buffer intensity $\beta=d n / d x$ in (6.22)
- $Y_{3} \Rightarrow$ enters $1^{\text {st }}$ derivative of $\beta \quad$ in (6.23)

### 5.3 Titration Curves

The closed-form expression in (5.32) contains all the information about the acidbase system. Plotting the equivalent fraction as a function of pH , i.e. $n=n(\mathrm{pH})$,
provides titration curves:

$$
\begin{equation*}
n=Y_{1}(\mathrm{pH})+\frac{w(\mathrm{pH})}{C_{T}} \quad \xrightarrow{C_{T} \rightarrow \infty} \quad n=Y_{1}(\mathrm{pH}) \tag{5.40}
\end{equation*}
$$

This formula for $n$ consists of two parts: $Y_{1}(x)$ as the contribution from the subsystem "acid" and $w(x)$ as the contribution from the subsystem " $\mathrm{H}_{2} \mathrm{O}$ ". As indicated by the arrow, the latter term vanishes for large $C_{T}$ values. In other words, for high-concentrated acids the formula simplifies to $n=Y_{1}$.

## Example: Carbonic Acid

The upper diagram in Fig 5.6 shows the titration curve of carbonic acid in the high- $C_{T}$ limit, where the simplified formula $n(\mathrm{pH})=Y_{1}=a_{1}+2 a_{2}$ applies. The corresponding ionization fractions $a_{j}$ - as the building blocks of $Y_{j}$ - are displayed in the bottom diagram.

Figure 5.6: Titration curve of carbonic acid in the "high- $C_{T}$ limit": $Y_{1}(\mathrm{pH})=$ $a_{1}+2 a_{2}$ (top diagram);
ionization fractions $a_{0}, a_{1}$, and $a_{2}$ (bottom diagram).

Fig 5.7 compares the titration curves in the "high- $C_{T}$ limit" (top diagram is the same as in Fig 5.6) with the general case, $n=Y_{1}+w / C_{T}$, for different values of $C_{T}$ (bottom diagram). Here too, the dark blue curve represents $Y_{1}$ as the "high- $C_{T}$ limit", i.e. $C_{T} / w \gg 1$.

## Example: HA, $\mathrm{H}_{2} \mathrm{~A}, \mathrm{H}_{3} \mathrm{~A}$

Titration curves of four common acids for different values of $C_{T}$ (including the high- $C_{T}$ case $n(\mathrm{pH})=Y_{1}$ as a dark blue curve) are shown in Fig 5.8.

Figure 5.7: Titration curves of carbonic acid for different $C_{T}$ values. Top diagram: the "pure-acid" case: $n(\mathrm{pH})=Y_{1}$ $=a_{1}+2 a_{2}$; bottom diagram: the "pure-acid" case $\left(C_{T} \rightarrow \infty\right)$ together with four finite $C_{T}$ values.

### 5.4 Equivalence Points: General Approach

### 5.4.1 Definitions

In § 3.2, equivalence points were introduced by equating two adjacent acid species [j]:2
$\mathrm{EP}_{\mathrm{j}}: \quad[j-1]=[j+1] \quad \Leftrightarrow \quad \mathrm{EP}_{\mathrm{n}}:[n-1]=[n+1] \quad$ (for integer $n=j$ )
semi- $\mathrm{EP}_{\mathrm{j}}:[j-1]=[j] \quad \Leftrightarrow \quad \mathrm{EP}_{\mathrm{n}}:\left[n-\frac{1}{2}\right]=\left[n+\frac{1}{2}\right] \quad$ (for half-integer $n=j-\frac{1}{2}$ )

This definition leads to simple formulas for the corresponding pH values (cf. § 3.2.2), whereby the so-called internal EPs are directly related to the acidity constants $K_{j}$ :

$$
\mathrm{EP}_{\mathrm{n}} \Leftrightarrow \mathrm{pH}_{\mathrm{n}}=\left\{\begin{array}{lll}
\frac{1}{2}\left(\mathrm{pK}_{\mathrm{n}}+\mathrm{pK}_{\mathrm{n}+1}\right) & \text { for } n=1,2, \ldots, N-1 & \text { (EP) }  \tag{5.43}\\
\mathrm{pK}_{\mathrm{n}+1 / 2} & \text { for } n=\frac{1}{2}, \frac{3}{2}, \ldots, N-\frac{1}{2} & \text { (semi-EP) }
\end{array}\right.
$$

## General Approach

The general approach is based on the equality of two chemical compounds (and not on the equality of two acid species as done in (5.41) and (5.42)):

$$
\begin{equation*}
\text { EP: } \quad[N \text {-protic acid }]_{\mathrm{T}}=[\text { strong base }]_{\mathrm{T}} \tag{5.44}
\end{equation*}
$$

which can be written as

$$
\begin{equation*}
\mathrm{EP}: \quad C_{T}=C_{B} \quad \text { or } \quad n=\frac{C_{B}}{C_{T}}=1 \tag{5.45}
\end{equation*}
$$

[^12]

Figure 5.8: Titration curves of four common acids for different values of $C_{T}$ (including the "pure-acid case" $\left.n(\mathrm{pH})=Y_{1}\right)$.

This defines the equivalence point $\mathrm{EP}_{1}$. The extension to other EPs and semi-EPs (for integer and half-integer $n$ ) is easy:

$$
\begin{equation*}
\mathrm{EP}_{\mathrm{n}}: \quad n=\frac{C_{B}}{C_{T}} \quad \text { for } n=0, \frac{1}{2}, 1, \frac{3}{2}, \ldots N \tag{5.46}
\end{equation*}
$$

The math relationship between the $\mathrm{EP}_{\mathrm{n}}$ and the corresponding $\mathrm{pH}_{\mathrm{n}}$ value is provided by the equivalence-fraction formula (5.32):

$$
\begin{equation*}
n=Y_{1}(\mathrm{pH})+\frac{w(\mathrm{pH})}{C_{T}} \quad \text { for } n=0, \frac{1}{2}, 1, \frac{3}{2}, \ldots N \tag{5.47}
\end{equation*}
$$

Plotting it as a function of pH yields the blue titration curve in Fig 5.9 (for $\mathrm{H}_{2} \mathrm{CO}_{3}$ with $\left.C_{T}=100 \mathrm{mM}\right)$. The small circles at integer and half-integer values of $n$ mark the assignment between $\mathrm{EP}_{\mathrm{n}}$ and $\mathrm{pH}_{\mathrm{n}}$. Since $\mathrm{H}_{2} \mathrm{CO}_{3}$ is a 2-protic acid there are $2 \times 2+1=5$ equivalence points in total.

Asymptotic Behavior: $C_{T} \rightarrow \infty$
If $C_{T}$ increases steadily, the second term in (5.47) approaches zero and we get the simple relationship:

$$
\begin{equation*}
\mathrm{EP}_{\mathrm{n}} \text { for } C_{T} \rightarrow \infty \quad \Longleftrightarrow 0=n-Y_{1}\left(\mathrm{pH}_{\mathrm{n}}\right) \quad \text { ("pure-acid case") } \tag{5.48}
\end{equation*}
$$

Figure 5.9: Titration curve of the diprotic acid $\mathrm{H}_{2} \mathrm{CO}_{3}$ based on (5.47) with EPs and semi-EPs located at integer and half-integer values of $n$.

In fact, according to (3.89), it offers the intimate relationship between the pH of an internal equivalence point and the acidity constants, as stated in (5.43). ${ }^{3}$ In other words, the "pure-acid case" from § 3.2 is immanent in (5.47) and comes to light when the "coupling term" $w / C_{T}$ disappears.

### 5.4.2 $\quad \mathrm{EP}_{\mathrm{n}}$ as Trajectories in $\mathrm{pH}-\mathrm{C}_{\mathrm{T}}$ Diagrams

Eq (5.47) can be rearranged into the form

$$
\begin{equation*}
C_{T}=\frac{w\left(\mathrm{pH}_{\mathrm{n}}\right)}{n-Y_{1}\left(\mathrm{pH}_{\mathrm{n}}\right)} \tag{5.49}
\end{equation*}
$$

Now it is possible to plot all $\mathrm{EP}_{\mathrm{n}}$ as distinct curves into a $\mathrm{pH}-C_{T}$ diagram (one curve for one integer or half-inter value of $n$ ). This is done in Fig 5.10 for four acids. The dashed curves and lines are approximations corresponding to the high- $C_{T}$ limit as displayed in Fig 3.3 on page 25.

Let's explain the general behavior of the $\mathrm{EP}_{\mathrm{n}}$ curves using the phosphoric acid (as a triprotic acid). This example is shown in Fig 5.11 and consists of two diagrams. In the top diagram, we have the two uncoupled (isolated) subsystems located at opposite ends of the $C_{T}$ scale:

- subsystem "acid": $\quad C_{T} \rightarrow \infty$
- subsystem " $\mathrm{H}_{2} \mathrm{O}$ ": $\quad C_{T} \rightarrow 0$

The bottom diagram in Fig 5.11 shows the situation in which both subsystems are coupled. Starting at pH 7 , the curves fan out when $C_{T}$ increases until they fit the "pure-acid" values at the top of the chart. The whole behavior is determined by (5.49).

The subsystem " $\mathrm{H}_{2} \mathrm{O}$ " overtakes the rule when $C_{T}$ drops below $10^{-7} \mathrm{M}$, which is just the amount of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$in pure water.

The two extremes (i.e. the two isolated subsystems) can be deduced from Eq (5.49) by setting either the nominator or the denominator to zero:

$$
C_{T}=\frac{w}{n-Y_{1}} \quad \Longleftrightarrow \begin{cases}w=0 & \Rightarrow C_{T}=0  \tag{5.50}\\ n-Y_{1}=0 & \Rightarrow C_{T} \rightarrow \infty\end{cases}
$$

[^13]

Figure 5.10: pH dependence of EPs and semi-EPs plotted as $C_{T}=f(\mathrm{pH})$ for four acids.

In math jargon, the corresponding pH values of the "pure acid" system (listed in Tab 3.2) are the poles (or singularities) of (5.49) or (5.50). On the other hand, the single EP of "pure $\mathrm{H}_{2} \mathrm{O}$ " is at the position where the nominator in (5.49) or (5.50) becomes zero (which is exactly at $\mathrm{pH}=7$ ):

$$
\begin{equation*}
\mathrm{EP} \text { of } \mathrm{H}_{2} \mathrm{O} \quad \Longleftrightarrow \quad 0=w(x) \quad \Longleftrightarrow \quad C_{T}=0 \tag{5.51}
\end{equation*}
$$

### 5.4.3 Summary: Systematics \& Classification

First. Equivalence points are "special equilibrium states" in which the equivalent fraction $n=C_{B} / C_{T}$ becomes an integer or half-integer value. An $N$-protic acid has a total of $2 N+1$ equivalence points:

$$
\begin{array}{lll}
\mathrm{EP}_{\mathrm{n}}: & C_{B} / C_{T}=n & \text { for } n=1,2, \ldots N \\
\operatorname{semi}-\mathrm{EP}_{\mathrm{n}}: & C_{B} / C_{T}=n & \text { for } n=\frac{1}{2}, \frac{3}{2}, \ldots\left(N-\frac{1}{2}\right)
\end{array}
$$

The trivial case $\mathrm{EP}_{0}$ refers to the base-free system with $\mathrm{pH}_{0}$ as the pH value of the acid with amount $C_{T}$ dissolved in water.

Second. Each $\mathrm{EP}_{\mathrm{n}}$ is characterized by a specific pH value, which we call $\mathrm{pH}_{\mathrm{n}}$. The algebraic relationship $\mathrm{EP}_{\mathrm{n}} \Leftrightarrow \mathrm{pH}_{\mathrm{n}}$ is given by $n=Y_{1}(\mathrm{pH})+w(\mathrm{pH}) / C_{T}$, i.e. (5.47), where $Y_{1}$ describes the acid and $w$ the water.

Third. The equivalent fraction $n=Y_{1}(\mathrm{pH})+w(\mathrm{pH}) / C_{T}$ (titration curve) represents the buffer capacity, as it will be shown later in Chapter 6. Its first pH -derivative is

Figure 5.11: pH dependence of EPs and semi-EPs of phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ for the uncoupled (top diagram) and the coupled system (bottom diagram).

the buffer intensity $\beta=d n / d \mathrm{pH}$. The EPs are the extreme points of $\beta$ :

$$
\begin{array}{llll}
\mathrm{EP}_{\mathrm{n}} & \text { integer } n & \Longleftrightarrow & \text { minimum buffer intensity } \beta \\
\text { semi- } \mathrm{EP}_{\mathrm{n}} & \text { half-integer } n & \Longleftrightarrow & \text { maximum buffer intensity } \beta
\end{array}
$$

Fourth. In the limiting case of high-concentrated acids $\left(C_{T} \rightarrow \infty\right)$, the general relationship simplifies to:

$$
\begin{equation*}
Y_{1}(\mathrm{pH})-n=0 \tag{5.54}
\end{equation*}
$$

This equation asserts the direct link between $\mathrm{pH}_{\mathrm{n}}$ and the acidity constants: ${ }^{4}$

$$
\left.\begin{array}{lll}
\mathrm{pH}_{\mathrm{n}}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{n}}+\mathrm{pK}_{\mathrm{n}+1}\right) & \text { for integer } n & \left(\mathrm{EP}_{\mathrm{n}}\right) \\
\mathrm{pH}_{\mathrm{n}}=\mathrm{pK}_{\mathrm{n}+1 / 2} & \text { for half-integer } n & (\text { semi-EP } \\
\mathrm{n}
\end{array}\right)
$$

These simple relationships are applicable for $C_{T}>10^{-3} \mathrm{M}$, but fail in very dilute acids when the influence of the water becomes dominant (and the general formula (5.47) must be used instead of (5.54)).
Fifth. An alternative definition of EPs is based on the equality of the concentrations of the species, as done in (5.41) and (5.42), and originally established in $\S 3.2$.1. This definition is an approximation which, strictly speaking, only applies to the high- $C_{T}$

[^14]case. (Nonetheless, in carbonate systems, for example, $\mathrm{EP}_{1}$ is often introduced as the equilibrium state for which $\left[\mathrm{CO}_{2}\right]=\left[\mathrm{CO}_{3}^{-2}\right]$ applies.)

Table 5.1 compares the two approaches to equivalence points. The left column summarizes the alternative definition based on the equality of species concentrations (as introduced in §3.2.1 for the simplified "pure acid" case). This is in sharp contrast to the general approach (right column in Table 5.1) where real chemical compounds are set equal.

Table 5.1: Comparison of two approaches to equivalence points.

|  | 1-component system ( $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ alone) | 3-component system $\left(\mathrm{H}_{\mathrm{N}} \mathrm{~A}+\mathrm{H}_{2} \mathrm{O}+\text { strong base }\right)$ |
| :---: | :---: | :---: |
|  | common, but approximate | general and strict |
|  | based on acid species $\begin{array}{lr} E P_{n}: & {[n-1]=[n+1]} \\ \text { semi-EP } n:[n-1 / 2]=[n+1 / 2] \end{array}$ | based on total amount of compounds $E P_{n}: n=\frac{[\text { strong base }]_{T}}{\left[H_{N} A\right]_{T}}=\frac{C_{B}}{C_{T}}$ |
| $\stackrel{0}{0}$$\stackrel{3}{3}$0 | $p H_{n}=\left\{\begin{array}{l} 1 / 2\left(p K_{n}+\mathrm{pK}_{n+1}\right) \Leftrightarrow E P \\ p K_{n+1 / 2} \quad \Leftrightarrow \text { semi-EP } \end{array}\right.$ | $C_{T}=\frac{w(x)}{n-Y_{1}(x)}$ |
|  | $\mathrm{C}_{\mathrm{T}} \rightarrow \infty$ |  |
|  | $\left(\mathrm{n}-\mathrm{Y}_{1}=0\right)$ |  |

Sixth. The concept was extended to zwitterionic acids in [1] (where (5.47) will become (4.7) in [1]). This provides a new perspective on Table 5.1: The simplified approach in the left column is related to isoelectric points (i.e. points that only exist for zwitterions, but not for common acids), while the approach in the right column refers to isoionic points.

Perfect is the enemy of Good Enough.
"Good for everything" is the same as "particularly good at nothing".

6.1 ANC and BNC ..... 57
6.2 Buffer Intensity ..... 61

### 6.1 ANC and BNC

### 6.1.1 EPs as Reference Points of ANC and BNC

The starting-point is the acid-base system of Chapter 5. An equilibrium state of the acid-base system with a given amount of $C_{T}$ is completely specified by the parameter $C_{B}$ or $n=C_{B} / C_{T}$. The main relationship is presented by (5.32) in $\S$ 5.2.2.

Buffer capacities are distances between two equilibrium states, expressed as the deviation from a reference point:

$$
\begin{equation*}
\Delta n=n-n_{\mathrm{ref}} \quad \text { or } \quad \Delta C_{B}=C_{B}-n_{\mathrm{ref}} C_{T} \tag{6.1}
\end{equation*}
$$

The reference point is usually an equivalence point $\mathrm{EP}_{\mathrm{n}}=j$ (with integer $j$ ). Thus we can set $n_{\text {ref }}=j$ and write:

$$
\begin{equation*}
\Delta n=n(x)-j \quad \text { or } \quad \Delta C_{B}=C_{B}-j \cdot C_{T} \quad(\text { with } j=0,1, \ldots) \tag{6.2}
\end{equation*}
$$

If $n_{\text {ref }}=0$, the equations collapse to $\Delta n=n$ and $\Delta C_{B}=C_{B}$. This legitimizes calling $n$ and $C_{B}$ buffer capacities; they measure the distance to $\mathrm{EP}_{0}$.

Two types of buffer capacities are in common use: the acid-neutralizing capacity (ANC) and the base-neutralizing capacity (BNC). The ANC is the amount of basicity of the system that can be titrated with a strong acid to a chosen equivalence point $\mathrm{EP}_{\mathrm{j}}\left(\right.$ at $\left.\mathrm{pH}_{\mathrm{j}}\right)$ :

$$
\begin{equation*}
[\mathrm{ANC}]_{n=j}=C_{B}(\mathrm{pH})-j \cdot C_{T} \tag{6.3}
\end{equation*}
$$

The small subscript $n$ in the symbol $[A N C]_{n}$ refers to the chosen reference point, usually $\mathrm{EP}_{\mathrm{n}}$ (with an integer $n$ ). In the special case of $n=0$, which corresponds to the base-free 2 -component system, the last term vanishes and the ANC becomes

$$
\begin{equation*}
[\mathrm{ANC}]_{0}=C_{B}(\mathrm{pH}) \tag{6.4}
\end{equation*}
$$

The BNC is the exact opposite of ANC:

$$
\begin{equation*}
[\mathrm{BNC}]_{\mathrm{n}}=-[\mathrm{ANC}]_{\mathrm{n}} \tag{6.5}
\end{equation*}
$$

The definition in (6.3) leads to a simple formula for ANC. Using (5.32) for $C_{B}(\mathrm{pH})=n C_{T}$ yields:

$$
\begin{equation*}
[\mathrm{ANC}]_{n=j}=\left\{Y_{1}(x)-j\right\} C_{T}+w(x) \tag{6.6}
\end{equation*}
$$

For example, the amount of strong acid (say HCl ) required to neutralize the system from startpoint $x\left(=10^{-\mathrm{pH}}\right)$ to a particular $\mathrm{EP}_{\mathrm{n}}$ (titration endpoint) is:

$$
\begin{align*}
& {[\mathrm{ANC}]_{0}=\left\{Y_{1}(x)-0\right\} C_{T}+w(x)=\left\{Y_{1}(x) C_{T}+w(x)\right\}-0 \cdot C_{T}}  \tag{6.7}\\
& {[\mathrm{ANC}]_{1}=\left\{Y_{1}(x)-1\right\} C_{T}+w(x)=\left\{Y_{1}(x) C_{T}+w(x)\right\}-1 \cdot C_{T}}  \tag{6.8}\\
& {\left[\mathrm{ANC}_{2}=\left\{Y_{1}(x)-2\right\} C_{T}+w(x)=\left\{Y_{1}(x) C_{T}+w(x)\right\}-2 \cdot C_{T}\right.} \tag{6.9}
\end{align*}
$$

The three ANC curves are shown in the top diagram of Fig 6.1 for carbonic acid $\left(C_{T}=10 \mathrm{mM}\right)$. The small circles at $\mathrm{pH}_{0}=4.2, \mathrm{pH}_{1}=8.2$, and $\mathrm{pH}_{2}=11.1$ mark the corresponding $\mathrm{EP}_{\mathrm{n}}$. The curves display the amount of strong acid (normalized by $C_{T}$ ) required to remove the inherent basicity and to attain $\mathrm{pH}_{0}$ (blue curve), $\mathrm{pH}_{1}$ (green curve), and $\mathrm{pH}_{2}$ (red curve). Of course, the highest amount (blue curve) is required to attain the lowest pH , namely $\mathrm{pH}_{0}=4.2$.

Negative ANC values indicate that the system's acidity should be removed to attain the $E P_{n}$ (which is the same as the addition of a strong base - see (6.5) for BNC). Curves of BNC are shown in the bottom diagram of Fig 6.1, which is the mirror image of the top diagram.

### 6.1.2 Titration Example

Given is a carbonic-acid system with $C_{T}=10 \mathrm{mM}$. The titration curve - based on (5.32) - is displayed in Fig 6.2. The three EPs for $n=0,1,2$ are marked by small yellow circles at $\mathrm{pH}_{0}=4.2, \mathrm{pH}_{1}=8.2$, and $\mathrm{pH}_{2}=11.1$.

Let's select two points on the titration curve as displayed in Fig 6.2:

- point (A) at $\mathrm{pH}=11.7$ (belongs to equivalent fraction $n(\mathrm{pH})=5 / 2$ )
- point (B) at $\mathrm{pH}=2.3 \quad$ (belongs to equivalent fraction $n(\mathrm{pH})=-1 / 2$ )

These two points (located on the opposite corners of the diagram) should be the starting points for the two types of titration:

- acidimetric titration with strong acid from (A) at $\mathrm{pH}=11.2 \Rightarrow \mathrm{pH}_{\mathrm{n}}$
- alkalimetric titration with strong base from (B) at $\mathrm{pH}=2.3 \Rightarrow \mathrm{pH}_{\mathrm{n}}$

Figure 6.1: Normalized $[\mathrm{ANC}]_{\mathrm{n}}$ and $[\mathrm{BNC}]_{\mathrm{n}}$ for carbonic acid with $C_{T}=$ 10 mM .

ANC. The required amount of strong acid (indicated by the green arrows in Fig 6.2) to attain $\mathrm{EP}_{1}, \mathrm{EP}_{2}$ and $\mathrm{EP}_{3}$ is just the acid-neutralizing capacity given in equations (6.7) to (6.9):

$$
\begin{align*}
& {[\mathrm{ANC}]_{0}=\{5 / 2-0\} \cdot C_{T}=25 \mathrm{mM}}  \tag{6.10}\\
& {[\mathrm{ANC}]_{1}=\{5 / 2-1\} \cdot C_{T}=15 \mathrm{mM}}  \tag{6.11}\\
& {[\mathrm{ANC}]_{2}=\{5 / 2-2\} \cdot C_{T}=5 \mathrm{mM}} \tag{6.12}
\end{align*}
$$

BNC. The required amount of strong base (indicated by the red arrows in Fig 6.2) to attain $\mathrm{EP}_{1}, \mathrm{EP}_{2}$ and $\mathrm{EP}_{3}$ is just the base-neutralizing capacity given in equations (6.7) to (6.9):

$$
\begin{align*}
{[\mathrm{BNC}]_{0} } & =\{-1 / 2-0\} \cdot C_{T}=5 \mathrm{mM}  \tag{6.13}\\
{[\mathrm{BNC}]_{1} } & =\{-1 / 2-1\} \cdot C_{T}=15 \mathrm{mM}  \tag{6.14}\\
{[\mathrm{BNC}]_{2} } & =\{-1 / 2-2\} \cdot C_{T}=25 \mathrm{mM} \tag{6.15}
\end{align*}
$$

The addition of a strong base is equivalent to the removal of a strong acid and vice versa.

### 6.1.3 Alkalinity and Acidity

In carbonate systems, ANC is known as alkalinity and BNC as acidity. Again, we have to distinguish between different types of alkalinity and acidity depending on the reference point $\mathrm{EP}_{\mathrm{n}}$ chosen. The carbonic acid has three integer-valued EPs; hence there are three types of alkalinity (cf. Fig 6.3):

Figure 6.2:
Titration curve for carbonic acid with [ANC] and [BNC] values.

total alkalinity (M alkalinity): $[$ Alk $]=[A N C]_{\mathrm{n}=0}$
P alkalinity:
$[\mathrm{P}-\mathrm{Alk}]=[\mathrm{ANC}]_{\mathrm{n}=1}$
caustic alkalinity:
[OH-Alk] $=[\mathrm{ANC}]_{\mathrm{n}=2}$
Correspondingly, there are three types of acidity:
mineral acidity: $[\mathrm{H}-\mathrm{Acy}]=[\mathrm{BNC}]_{\mathrm{n}=0}$
$\mathrm{CO}_{2}$ acidity:
acidity:

$$
\begin{array}{ll}
{\left[\mathrm{CO}_{2} \text { - } \mathrm{Acy}\right]} & =[\mathrm{BNC}]_{\mathrm{n}=1} \\
{[\mathrm{Acy}]} & =[\mathrm{BNC}]_{\mathrm{n}=2}
\end{array}
$$

Figure 6.3: Titration curve $n=n(\mathrm{pH})$ for carbonic acid ( $C_{T}=$ 10 mM ) with equivalence points and the corresponding types of alkalinity and acidity.

Alkalinity and acidity are complementary. From (6.5) we get:

$$
\begin{array}{rlll}
{[\mathrm{ANC}]_{0}} & =-[\mathrm{BNC}]_{0} & \Longrightarrow & {[\mathrm{Alk}]} \\
{[\mathrm{ANC}]_{1}} & =-[\mathrm{BNC}]_{1} & \Longrightarrow & {[\mathrm{H}-\mathrm{Acy}]} \\
{[\mathrm{P}-\mathrm{Alk}]} & \left.=-[\mathrm{CO}]_{2} \text {-Acy }\right] \\
{[\mathrm{ANC}]_{2}} & =-[\mathrm{BNC}]_{2} & \Longrightarrow & {[\mathrm{OH}-\mathrm{Alk}]}
\end{array}=-[\mathrm{Acy}] .
$$

Of all three types of alkalinity, total alkalinity is the most important; it is given by

$$
\begin{equation*}
[\mathrm{Alk}] \equiv[\mathrm{ANC}]_{0}=C_{B}=n C_{T} \tag{6.16}
\end{equation*}
$$

Using (6.6), the difference between total alkalinity (M-alkalinity) and P-alkalinity yields the amount of $C_{T}$ as follows:

$$
\begin{equation*}
[\mathrm{Alk}]-[\mathrm{P}-\mathrm{Alk}]=[\mathrm{ANC}]_{0}-[\mathrm{ANC}]_{1}=C_{T} \quad(=\mathrm{DIC}) \tag{6.17}
\end{equation*}
$$

In carbonate systems, this is just the molar concentration of dissolved inorganic carbon (DIC).

### 6.1.4 pH as Reference Point of ANC and BNC

In § 6.1.1, ANC and BNC have been defined with respect to an equivalence point $E P_{n}$. ANC and BNC can also be defined with respect to a particular pH value (which can be any chosen value). In practice it is common to use the pH of the equivalence points $\mathrm{EP}_{0}$ and $\mathrm{EP}_{1}$ of the carbonate system:

$$
\begin{array}{ll}
\mathrm{EP}_{0}: & \mathrm{pH}=4.3 \\
\mathrm{EP}_{1}: & \mathrm{pH}=8.2
\end{array}
$$

The two EPs are shown as yellow dots in Fig 6.3. The usefulness of this choice is that these are the pH values of common indicators: indicator methylorange (titration endpoint 4.2 to 4.5 ) and indicator phenolphthalein (titration endpoint 8.2 to 8.3). The measured amount of strong acid or strong base to reach these endpoints are called:

| ANC to $\mathrm{pH} 4.3:$ | $[\mathrm{ANC}]_{\mathrm{pH} \mathrm{4.3}}$ | $\simeq[\mathrm{Alk}]$ |
| :--- | :--- | :--- |
| ANC to pH 8.2: | $[\mathrm{ANC}]_{\mathrm{pH} 8.2}$ | $\simeq[\mathrm{P}-\mathrm{Alk}]$ |
| BNC to $\mathrm{pH} 4.3:$ | $[\mathrm{BNC}]_{\mathrm{pH} 4.3}$ | $\simeq-[\mathrm{Alk}]$ |
| BNC to $\mathrm{pH} 8.2:$ | $[\mathrm{BNC}]_{\mathrm{pH} 8.2}$ | $\simeq-[\mathrm{P}-\mathrm{Alk}]$ |

The measured "ANC to pH 4.3 " corresponds to the total alkalinity (or M-alkalinity) of the system; the measured "ANC to pH 8.2 " to the P-alkalinity. The abbreviation " M " refers to the indicator methylorange and " P " to phenolphthalein.

### 6.2 Buffer Intensity

### 6.2.1 From Buffer Capacity to Buffer Intensity

Let us start with the normalized buffer capacity in (6.2). Using (5.32) yields:

$$
\begin{equation*}
\text { normalized buffer capacity: } \quad \Delta n(\mathrm{pH})=\left\{Y_{1}(\mathrm{pH})-j\right\}+\frac{w(\mathrm{pH})}{C_{T}} \tag{6.18}
\end{equation*}
$$

The derivative with respect to pH gives:

$$
\begin{array}{lll}
\text { normalized buffer intensity: } & \beta \equiv \frac{\mathrm{d} \Delta n}{\mathrm{dpH}}=\frac{\mathrm{d} n}{\mathrm{dpH}} & \text { (unitless) } \\
\text { buffer intensity: } & \beta_{C} \equiv \frac{\mathrm{~d} C_{B}}{\mathrm{dpH}}=\beta C_{B} & \text { (in mM) } \tag{6.20}
\end{array}
$$

[Note: The last equation is valid if $C_{T}=$ const (standard case), otherwise we have to use $\mathrm{d} C_{B} / \mathrm{dpH}=\beta C_{T}+n\left(\mathrm{~d} C_{T} / \mathrm{dpH}\right)$.]

The acid-neutralizing capacity is re-established by integrating $\beta_{C}$ over a definite pH interval (usually starting from an equivalence point $\mathrm{EP}_{\mathrm{n}}$ ):

$$
\begin{equation*}
[\mathrm{ANC}]_{\mathrm{n}}=\int_{\mathrm{pH}_{\mathrm{n}}}^{\mathrm{pH}} \beta_{C}(\widetilde{\mathrm{pH}}) \mathrm{d} \widetilde{\mathrm{pH}} \tag{6.21}
\end{equation*}
$$

To perform the $1^{\text {st }}$ and $2^{\text {nd }} \mathrm{pH}$ derivative of (6.18) we apply the formulas in Appendix B.4, in particular (B.40) and (B.41) for $w(\mathrm{pH})$ as well as (B.50) and (B.53) for $Y_{1}(\mathrm{pH})$. We get:

$$
\begin{align*}
\text { norm. buffer intensity: } & \beta(x) & \equiv \frac{\mathrm{d} n}{\mathrm{dpH}}=(\ln 10)\left(Y_{2}-Y_{1}^{2}+\frac{w+2 x}{C_{T}}\right)  \tag{6.22}\\
1^{\text {st }} \text { derivative of } \beta: & \frac{\mathrm{d} \beta}{\mathrm{~d} \mathrm{pH}} & =(\ln 10)^{2}\left(Y_{3}-3 Y_{1} Y_{2}+2 Y_{1}^{3}+\frac{w}{C_{T}}\right) \tag{6.23}
\end{align*}
$$

Fig 6.4 displays the titration curve (blue) together with the buffer intensity $\beta$ (green) and its $1^{\text {st }}$ derivative (red) for the $\mathrm{H}_{2} \mathrm{CO}_{3}$ system with $C_{T}=100 \mathrm{mM}$. The calculations are performed using equations (6.18), (6.22), and (6.23). The small circles indicate the EPs and semi-EPs. The EPs are the extremum points of $\beta$ :

$$
\begin{array}{llll}
\mathrm{EP}_{\mathrm{n}}: & (\text { integer } n) & \Leftrightarrow & \text { minimum buffer intensity } \beta \\
\text { semi-EP } & (\text { half-integer } n) & \Leftrightarrow & \text { maximum buffer intensity } \beta
\end{array}
$$

Figure 6.4: Optimal buffer range of the $\mathrm{H}_{2} \mathrm{CO}_{3}$ system with $C_{T}$ $=100 \mathrm{mM}$.

A good pH buffer should mitigate pH changes when the system is attacked by a strong base or strong acid. It means that the pH change, $\Delta \mathrm{pH}$, should be small when $n=C_{B} / C_{T}$ changes by $\Delta n$. In other words, the slope of the titration curve in Fig 6.4, $\Delta n / \Delta \mathrm{pH}$, should be large for maximum buffering capability. The buffer intensity,
$\beta=\mathrm{d} n / \mathrm{dpH}$, is just the measure of this slope. Thus, the pH at the point where $\beta$ reaches its maximum signals the optimal buffer range (bounded by $\mathrm{pH}_{\max } \pm 1$ ).

More examples are given in Fig 6.5 and Fig 6.7. Since each titration curve (blue) is an ever-increasing function, its pH derivative, i.e. the buffer intensity $\beta$, is always positive (green curves).

Figure 6.5: Normalized buffer capacity (blue), buffer intensity (green), and $\mathrm{d} \beta / \mathrm{dpH}$ (red) for four acids and $C_{T} \rightarrow \infty$ (i.e. $C_{T} / w \gg 1$ ). Maxima and minima of the buffer intensity $\beta$ (green) are located at zeros of $\mathrm{d} \beta / \mathrm{dpH}$ (small circles on red curves).

### 6.2.2 Minima and Maxima (High- $C_{T}$ Limit)

Equations (6.18), (6.22) and (6.23) simplify for large values of $C_{T}$ ("high- $C_{T}$ limit"), where the last term in the above equations (containing $C_{T}$ in the denominator) vanish. Hence, for $C_{T} \gg w$ we have:

$$
\begin{array}{ll}
\text { norm. buffer capacity: } & \Delta n(\mathrm{pH})=Y_{1}(\mathrm{pH})-j \\
\text { norm. buffer intensity: } & \beta(\mathrm{pH})=(\ln 10)\left(Y_{2}-Y_{1}^{2}\right) \\
1^{\text {st }} \text { derivative of } \beta \text { : } & \frac{\mathrm{d} \beta}{\mathrm{~d} \mathrm{pH}}=(\ln 10)^{2}\left(Y_{3}-3 Y_{1} Y_{2}+2 Y_{1}^{3}\right) \tag{6.26}
\end{array}
$$

These are smooth functions made of $Y_{1}, Y_{2}$, and $Y_{3}$ alone. The behavior of $Y_{L}$ is entirely determined by the set of the acid's equilibrium constants $K_{j}$, or alternatively, by the internal equivalence points $\mathrm{EP}_{\mathrm{n}}$ as given in (3.82) and (3.83):

$$
\begin{array}{lll}
\text { semi- } \mathrm{EP}_{\mathrm{j}} \text { at } \mathrm{pK} \mathrm{~K}_{\mathrm{j}}: & Y_{L}=\frac{1}{2}\left\{(j-1)^{L}+j^{L}\right\} & \left(n=j-\frac{1}{2}\right) \\
\mathrm{EP}_{\mathrm{j}} \text { at } \mathrm{pH}_{\mathrm{j}} \equiv \frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right): & Y_{L} \simeq j^{L} & (n=j) \tag{6.28}
\end{array}
$$

Inserting it into (6.25) yields

$$
\begin{align*}
& \frac{\beta\left(\mathrm{pK}_{\mathrm{j}}\right)}{\ln 10}=Y_{2}\left(\mathrm{pK}_{\mathrm{j}}\right)-Y_{1}^{2}\left(\mathrm{pK}_{\mathrm{j}}\right)=\left\{j(j-1)+\frac{1}{2}\right\}-\left\{j(j-1)+\frac{1}{4}\right\}=\frac{1}{4}  \tag{6.29}\\
& \frac{\beta\left(\mathrm{pH}_{\mathrm{j}}\right)}{\ln 10}=Y_{2}\left(\mathrm{pH}_{\mathrm{j}}\right)-Y_{1}^{2}\left(\mathrm{pH}_{\mathrm{j}}\right)=j^{2}-j^{2}=0 \tag{6.30}
\end{align*}
$$

Now, we prove that these equivalence points are extremum points of the buffer intensity. In math, the maximum or minimum is known to be the point at which the slope (i.e. the derivative) of a function becomes zero. Hence, local maxima and minima of the buffer intensity $\beta(\mathrm{pH})$ occur at pH values where $\mathrm{d} \beta / \mathrm{dpH}=0$. The derivative itself is given in (6.26), where we focus on $Y_{3}-3 Y_{1} Y_{2}+2 Y_{1}^{3}$.

For the semi- $\mathrm{EP}_{\mathrm{n}}$ with half-integer $n=j-\frac{1}{2}$, we get from (6.27):

$$
\begin{align*}
Y_{3}-3 Y_{1} Y_{2}+2 Y_{1}^{3} & =\frac{1}{2}\left\{(j-1)^{3}+j^{3}\right\}-3\left(j-\frac{1}{2}\right)\left\{j(j-1)+\frac{1}{2}\right\}+2\left(j-\frac{1}{2}\right)^{3} \\
& =0 \quad \text { at } \mathrm{pH}=\mathrm{pK}_{\mathrm{j}} \text { for } j=1,2, \ldots N \tag{6.31}
\end{align*}
$$

For the $\mathrm{EP}_{\mathrm{n}}$ with integer $n=j$, we get from (6.28):

$$
\begin{align*}
Y_{3}-3 Y_{1} Y_{2}+2 Y_{1}^{3} & =j^{3}-3 j j^{2}+2 j^{3} \\
& =0 \quad \text { at } \mathrm{pH}=\mathrm{pH}_{\mathrm{j}} \text { for } j=1,2, \ldots N-1 \tag{6.32}
\end{align*}
$$

Hence, the zeros of $\mathrm{d} \beta / \mathrm{dpH}$ occur exactly at the internal equivalence points $\mathrm{EP}_{\mathrm{n}}$ for both integer and half-integer $n$. To decide whether the zeros indicate a maximum or minimum, we need the next higher derivative $\mathrm{d}^{2} \beta / \mathrm{dpH}^{2}$ (or $d^{3} Y_{1} / \mathrm{dpH}^{3}$, which is presented in (B.54) in Appendix B.4.3.

## Summary

The following assignment is valid for $C_{T} / w \gg 1$ :

$$
\begin{array}{llll}
\text { semi- }-\mathrm{EP}_{\mathrm{j}} \text { at } \mathrm{pK} & \Longleftrightarrow & \text { maximum of } \beta & \left(\mathrm{d}^{3} Y_{1} /\left.\mathrm{dpH}^{3}\right|_{\mathrm{pK}_{\mathrm{j}}}<0\right) \\
\mathrm{EP}_{\mathrm{j}} \text { at } \mathrm{pH}_{\mathrm{j}} & \Longleftrightarrow & \text { minimum of } \beta & \left(\mathrm{d}^{3} Y_{1} /\left.\mathrm{dpH}^{3}\right|_{\mathrm{pH}_{\mathrm{j}}}>0\right) \tag{6.34}
\end{array}
$$

The buffer intensity attains its maximum at semi-equivalence points located at $\mathrm{pK}_{\mathrm{j}}$. The actual values of $\beta$ at this extrema were already presented in (6.29) and (6.30):

$$
\begin{array}{lll}
\operatorname{maxima} \text { of } \beta \text { at semi- } \mathrm{EP}_{\mathrm{j}}: & \beta_{\max }=\frac{\ln 10}{4} \simeq 0.576 & \text { for half-integer } n \\
\text { minima of } \beta \text { at } \mathrm{EP}_{\mathrm{j}}: & \beta_{\min }=0 & \text { for } n=1,2, \ldots N-1 \tag{6.36}
\end{array}
$$

This behavior of the buffer intensity is illustrated in Fig 6.5 for four acids. The maxima of $\beta$ (green curve) are indicated by the corresponding $\mathrm{pK}_{\mathrm{j}}$ values, where the zeros of $\mathrm{d} \beta / \mathrm{dpH}$ (red curve) are marked by small blue dots.

## Example: Carbonate System

The carbonate system, as shown in the bottom-left diagram of Fig 6.5, has two semi-EPs. Hence, there are two maxima of the buffer intensity (green curve) located at $\mathrm{pK}_{1}=6.35$ and $\mathrm{pK}_{2}=10.33$, while the minimum of $\beta$ is located at $\mathrm{pH}_{1}=$ $\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right)=8.34$ (which is an integer-valued EP).

### 6.2.3 The General Case

$\S 6.2 .2$ was focused on large values of $C_{T}(\gg w)$. Now, the more realistic case of small $C_{T}$ values considers the effect of the autoprotolysis of $\mathrm{H}_{2}$ Othrough the last term in (6.18), (6.22) and (6.23). The results are displayed in diagrams, each containing three curves:

```
- \(n(\mathrm{pH}) \quad\) buffer capacity \(\quad \mathrm{Eq}(6.18)\) (blue curve)
- \(\beta=\mathrm{d} n / \mathrm{dpH}\) buffer intensity \(\quad \mathrm{Eq}(6.22)\) (green curve)
- \(\mathrm{d} \beta / \mathrm{dpH} \quad 1^{\text {st }}\) derivative of \(\beta \quad \mathrm{Eq}\) (6.23) (red curve)
```

All three quantities are unitless. The small blue circles mark the zeros of $\mathrm{d} \beta / \mathrm{dpH}$, which correspond to the minima and maxima of the buffer intensity $\beta$.

## Example: Carbonate System

Given is the carbonic acid system with $C_{T}=100 \mathrm{mM}, 10 \mathrm{mM}$, and $1 \mathrm{mM} \mathrm{H} \mathrm{H}_{2} \mathrm{CO}_{3}$; the results are shown in Fig 6.6.

Figure 6.6: Titration curve $n(\mathrm{pH})$, buffer intensity $\beta$, and $\mathrm{d} \beta / \mathrm{dpH}$ for three $C_{T}$ values of the carbonate system.

## Example: Four Common Acids

Fig 6.7 to Fig 6.9 displays the results for four common acids with an amount of $C_{T}=100 \mathrm{mM}, 10 \mathrm{mM}$, and 1 mM . These results should be compared with the curves for the case $C_{T} \rightarrow \infty$ in Fig 6.5 on page 63.

Figure 6.7: Titration curve (blue), buffer intensity (green), and $\mathrm{d} \beta / \mathrm{dpH}$ (red) for four common acids with $C_{T}=100 \mathrm{mM}$.

Figure 6.8: Titration curve (blue), buffer intensity (green), and $\mathrm{d} \beta / \mathrm{dpH}$ (red) for four common acids with $C_{T}=10 \mathrm{mM}$.

Figure 6.9: Titration curve (blue), buffer intensity (green), and $\mathrm{d} \beta / \mathrm{dpH}$ (red) for four common acids with $C_{T}=1 \mathrm{mM}$.

### 7.1 Relationships between $\mathrm{pH}, C_{T}$, and Alkalinity

The actual equilibrium state of a diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ (i.e. the concentrations of the three aqueous species $[j]: \mathrm{H}_{2} \mathrm{~A}, \mathrm{HA}^{-}$, and $\mathrm{A}^{-2}$ ) is completely controlled by two parameters chosen from the triple ( $C_{T}, n, \mathrm{pH}$ ) or ( $C_{T}, C_{B}, \mathrm{pH}$ ), where $C_{B}={ }_{n} C_{T}=$ Alk (see (6.16)). Once we know two of them, the third is inevitably fixed:

$$
\begin{array}{lll}
\mathrm{pH}\left(C_{T}, n\right)=-\lg x_{n} \text { with } x_{n} \text { as positive root of }(5.38), & {[j]=C_{T} a_{j}} \\
\mathrm{pH}\left(C_{T}, \mathrm{Alk}\right)=-\lg x_{n} \text { with } x_{n} \text { as positive root of }(5.39), & {[j]=C_{T} a_{j}} \\
n\left(C_{T}, \mathrm{pH}\right) & =a_{1}+2 a_{2}+w / C_{T}, & {[j]=C_{T} a_{j}} \\
\operatorname{Alk}\left(C_{T}, \mathrm{pH}\right)=C_{T}\left(a_{1}+2 a_{2}\right)+w, & {[j]=C_{T} a_{j}} \\
C_{T}(n, \mathrm{pH})=w /\left(n-a_{1}-2 a_{2}\right), & {[j]=\left(w /\left(n-a_{1}-2 a_{2}\right)\right) a_{j}} \\
C_{T}(\mathrm{Alk}, \mathrm{pH})=(\mathrm{Alk}-w) /\left(a_{1}+2 a_{2}\right), & {[j]=(\mathrm{Alk}-w) /\left(a_{1}+2 a_{2}\right) a_{j}} \tag{7.6}
\end{array}
$$

These nonlinear relationships are displayed for carbonic acid in Fig 7.1 and Fig 7.2. The diagrams show all possible combinations of 1 dependent and 2 independent variables taken from the triple $C_{T}, \mathrm{pH}$, and $n\left(\right.$ or $\mathrm{Alk}=n C_{T}$ ). Note how the "simple transformation" of the variable $n$ into Alk $=n C_{T}$ dramatically changes the shape of the curves in Fig 7.2 (compared to Fig 7.1).

Figure 7.1: Relationships between $\mathrm{pH}, C_{T}$, and $n$ for the carbonic acid system (at $25^{\circ} \mathrm{C}$ ).

### 7.2 Three Equivalence Points

The carbonate system controls the pH in most natural waters. Due to the existence of three major carbonate species $\left(\mathrm{CO}_{2}, \mathrm{HCO}_{3}^{-}, \mathrm{CO}_{3}^{-2}\right)$, textbooks usually focus on three equivalence points:

$$
\begin{array}{lll}
\mathrm{EP}_{0} & \text { (also known as EP of } \left.\mathrm{CO}_{2}\right): & {\left[\mathrm{H}^{+}\right]=\left[\mathrm{HCO}_{3}^{-}\right]} \\
\mathrm{EP}_{1} & \text { (also known as EP of } \left.\mathrm{HCO}_{3}^{-}\right): & {\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]=\left[\mathrm{CO}_{3}^{-2}\right]} \\
\mathrm{EP}_{2} & \text { (also known as EP of } \left.\mathrm{CO}_{3}^{-2}\right): & {\left[\mathrm{HCO}_{3}^{-}\right]=\left[\mathrm{OH}^{-}\right]}
\end{array}
$$

The identification of EPs as points of equal species concentrations, as done here on the right-hand side, is an approximation, albeit a very good one. In BJERRUM plots, these are points of intersections of two concentration curves. Fig 7.3 maps the intersection points from the two lower diagrams (one for $C_{T}=10^{-3} \mathrm{M}$ and one for $10^{-4} \mathrm{M}$ ) upwards into the $\mathrm{pH}-C_{T}$ diagram where they constitute the small circles on the EP trajectories.

Here, we observe a different behavior for the two external equivalence points ( $\mathrm{EP}_{0}$ and $\mathrm{EP}_{2}$ ) on the one hand and for the single internal equivalence point $E P_{1}$ on the other hand.

Figure 7.2: Relationships between $\mathrm{pH}, C_{T}$, and Alk for the carbonic acid system (at $25^{\circ} \mathrm{C}$ ).

## Two External Equivalence Points: $\mathbf{E P}_{0}$ and $\mathbf{E P}_{2}$

The two external EPs depend on $C_{T}$ :

|  | $C_{T}=10^{-4} \mathrm{M}$ | $C_{T}=10^{-3} \mathrm{M}$ |
| :--- | :---: | :---: |
| $\mathrm{EP}_{0}$ at pH | 5.18 | 4.68 |
| $\mathrm{EP}_{2}$ at pH | 9.86 | 10.56 |

## One Internal Equivalence Point: EP $_{1}$

The $\mathrm{EP}_{1}$ does not depend on $C_{T}$. The intersection points of the $\mathrm{CO}_{2}$ and $\mathrm{CO}_{3}^{-2}$ curves in the two lower diagrams in Fig 7.3 are both at the same fixed pH value of $\frac{1}{2}\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}\right)=8.34$, which belongs to the high- $C_{T}$ limit of the red curve in the upper diagram. Only when we decrease $C_{T}$ further below $10^{-4} \mathrm{M}$, i.e. for very dilute acids, the simple relationship $\left[\mathrm{CO}_{2}\right]=\left[\mathrm{CO}_{3}^{-2}\right]$ no longer works correctly.

Figure 7.3: Equivalence points of the carbonate system. Assignment of the EPs in the upper $\mathrm{pH}-C_{T}$ diagram to the intersection points of curves of species concentrations (two lower diagrams).

### 7.3 Acid-Base Titration with $\mathrm{H}_{2} \mathrm{CO}_{3}$ as Titrant

During titration, a titrant is added to the analyte to reach the target pH or equivalence point. Two cases (which are opposite of each other) will be considered:

$$
\begin{array}{ll}
\operatorname{var} A: & 100 \mathrm{mM} \mathrm{H} \\
& \mathrm{CO}_{3} \text { solution is titrated by a strong base/acid }(\mathrm{NaOH} \\
& \text { and } \mathrm{HCl})
\end{array}
$$

var B: 100 mM NaOH solution is titrated by $\mathrm{H}_{2} \mathrm{CO}_{3}$
In $\operatorname{var} A$ the $C_{T}$ is kept fixed (and $C_{B}$ is varied), while in $\operatorname{var} B$ the $C_{B}$ is kept fixed (and $C_{T}$ is varied). The aim is to calculate the carbonate speciation as a function of pH . In both cases, we start with the ionization fractions $a_{j}$ (based on (3.58) and shown in the bottom left diagram in Fig 3.4), which are the same for $\operatorname{var} A$ and var $B$. From each $a_{j}$, we then get the species concentration by multiplication with $C_{T}:[j]=C_{T} a_{j}$. The main point is that var $A$ and $\operatorname{var} B$ differ in the $C_{T}$ value:

$$
\begin{array}{lll}
\operatorname{var} A: & C_{T}=\text { const } & \text { with } C_{T}=100 \mathrm{mM} \\
\operatorname{var} B: & C_{T}=\left(C_{B}-w\right) / Y_{1} & \text { with } C_{B}=100 \mathrm{mM}
\end{array}
$$

where the last line is taken from (5.32).
The obtained species distribution is displayed in Fig 7.4: $\operatorname{var} A$ (left) and $\operatorname{var} B$ (right). The gray curve represents the total concentration $C_{T}$ as the sum of all

titration of 100 mM NaOH by $\mathrm{H}_{2} \mathrm{CO}_{3}$

$$
C_{T}=\left(C_{B}-w\right) / Y_{1}
$$

Figure 7.4: Species distribution of $\mathrm{H}_{2} \mathrm{CO}_{3}$ as a function of pH for $\operatorname{var} A$ (left) and $\operatorname{var} B$ (right). Top diagrams: concentrations in linear scale; bottom diagrams: logarithmic scale.
carbonate species. The top and bottom diagrams only differ by the concentration scale: the $y$-axis is linear or logarithmic, respectively.

Although both variants rely on exactly the same ionization fractions, the pH dependence of the species in $\operatorname{var} A$ (left) and $\operatorname{var} B$ differ significantly. While the species distribution in $\operatorname{var} A$ (top left) replicates the shapes of the ionization fractions, $\operatorname{var} B$ is completely out of line. [Note: In $\operatorname{var} B, \mathrm{pH}<5$ is not available in practice.]

### 7.4 Open vs Closed $\mathrm{CO}_{2}$ System

In an open $\mathrm{CO}_{2}$ system, the solution is in equilibrium with the $\mathrm{CO}_{2}$ of the atmosphere. Let us compare it with the closed system:
var A: titration of $100 \mathrm{mM} \mathrm{H} \mathrm{H}_{2} \mathrm{CO}_{3}$ solution as "closed $\mathrm{CO}_{2}$ system" (same as in § 7.3)
var $C$ : titration of $100 \mathrm{mM} \mathrm{H}_{2} \mathrm{CO}_{3}$ solution as "open $\mathrm{CO}_{2}$ system"
As in § 7.3, we start with the same ionization fractions $a_{j}$ for both $\operatorname{var} A$ and $\operatorname{var} C$, as shown in in the left bottom diagram in Fig 3.4. As in $\S 7.3$, the two variants differ only in the functional dependence of $C_{T}$, which will be derived now.

The "open system" is described by Henry's law that partitions the $\mathrm{CO}_{2}$ between the aqueous and gas phase: $\mathrm{CO}_{2}(\mathrm{aq})$ is proportional to $\mathrm{CO}_{2}(\mathrm{~g})$, whereas $\mathrm{CO}_{2}(\mathrm{aq})$ is the undissociated acid $\mathrm{H}_{2} \mathrm{CO}_{3}$, i.e., the uncharged species [0]. Thus, we can write:

$$
\begin{equation*}
[0]=K_{H} \cdot P \quad \text { with } \quad K_{H}=10^{-1.47} \mathrm{M} / \mathrm{atm}\left(\text { at } 25^{\circ} \mathrm{C}\right) \tag{7.7}
\end{equation*}
$$

and with $P$ as the partial $\mathrm{CO}_{2}$ pressure. Using [0] $=C_{T} a_{0}$, we obtain:

$$
\begin{equation*}
\text { open } \mathrm{CO}_{2} \text { system : } \quad C_{T}=\frac{K_{H} P}{a_{0}} \tag{7.8}
\end{equation*}
$$

Thus, the two variants differ in the $C_{T}$ value:

```
\(\operatorname{var} A: \quad C_{T}=\) const \(\quad\) with \(C_{T}=100 \mathrm{mM}\)
\(\operatorname{var} C: \quad C_{T}=K_{H} P / a_{0} \quad\) with \(P=0.00039 \mathrm{~atm}\left(=10^{-3.408} \mathrm{~atm}\right)\)
```

The carbonate speciation is displayed in Fig 7.5: $\operatorname{var} A$ (left) and $\operatorname{var} C$ (right).

Figure 7.5: Species distribution of $\mathrm{H}_{2} \mathrm{CO}_{3}$ as a function of pH for $\operatorname{var} A$ (left) and $\operatorname{var} C$ (right). Top diagrams: concentrations in linear scale; bottom diagrams: log scale.

The conclusions are similar to $\S 7.3$. Although both variants rely on exactly the same ionization fractions, the pH dependence of the species in $\operatorname{var} A$ and $\operatorname{var} C$ is completely different. While the species distribution in $\operatorname{var} A$ (top left) replicates the shapes of the ionization fractions, var $C$ does not. The more alkaline the solution becomes, the more $\mathrm{CO}_{2}$ is sucked out of the atmosphere (which increases the $C_{T}$ exponentially). [Note: In $\operatorname{var} C, \mathrm{pH}<5$ is not available in practice.]

## Resume

The three variants (var $A, \operatorname{var} B, \operatorname{var} C$ ) discussed in the last two Sections exhibit the universality of the ionization fractions $a_{j}$ (shown in the bottom left diagram in Fig 3.4). They are independent of the chosen model, i.e. the functional dependence of $C_{T}$.

### 7.5 Seawater

The analytical formulas in (5.32) and (5.49) are based on the assumption that activities could be replaced by concentrations, $\{j\} \rightarrow[j]$. This is valid either for dilute systems with near-zero ionic strength ( $I \simeq 0$ ), or for non-dilute systems when the thdyn equilibrium constants are replaced by conditional constants, $K \rightarrow{ }^{c} K$.

Seawater has $I \simeq 0.7 \mathrm{M}$, which is at the upper limit of the validity range of common activity models (as discussed in Appendix A.2). Hence, in oceanography, chemists prefer conditional equilibrium constants ${ }^{c} K$. In the literature, there are several compilations for ${ }^{c} K$; one example is given in Table 7.1.

Table 7.1: Thermodynamic and conditional equilibrium constants for $\mathrm{H}_{2} \mathrm{CO}_{3}$ in pure water and seawater (at $25^{\circ} \mathrm{C}, 1 \mathrm{~atm}$ ); ${ }^{c} K$ values from [40].

|  | thdyn $K$ | conditional ${ }^{c} K$ |
| :--- | :---: | :---: |
|  | (pure water, $I=0$ ) | (seawater, $I=0.7 \mathrm{M}$ ) |
| $\mathrm{pK}_{1}$ | 5.18 | 6.0 |
| $\mathrm{pK}_{2}$ | 10.33 | 9.1 |
| $\mathrm{pK}_{\mathrm{w}}$ | 14.0 | 13.1 |

Fig 7.6 (left diagram) compares the results calculated by (5.49) for both the standard case (solid lines based on thdyn equilibrium constants $K$ ) and seawater (dashed lines based on conditional constants ${ }^{c} K$ ). The solid curves in Fig 7.6 are identical to the solid curves for $n=0,1$, and 2 shown in the bottom left diagram in Fig 5.10.

Figure 7.6: $\mathrm{pH}-C_{T}$ diagrams of the carbonic-acid system. Left: $\mathrm{H}_{2} \mathrm{CO}_{3}$ in pure water (solid lines) vs $\mathrm{H}_{2} \mathrm{CO}_{3}$ in seawater (dashed lines). Right: closed-form expression (5.49) vs numerical model (dots).

### 7.6 From Ideal to Real Solutions

All calculations so far (except in § 7.5) were performed for the ideal case (i.e., no activity corrections, no aqueous complexation). Modern hydrochemistry software
does not adhere to those restrictions; they perform activity corrections "automatically". In this respect, they are able to predict the relationship between pH and a given $C_{T}$ for real systems more accurately.

Given is a carbonic acid system titrated with NaOH . Fig 7.6 (right diagram) compares the results of the analytical formula (5.49) (solid lines) with the numericalmodel predictions (dots) using PhreeqC [33] or aqion [37]. (Similar results are obtained when NaOH is replaced by KOH .)

As expected, deviations between the ideal and the real case only occur at high $C_{T}$ values. There are two reasons: (i) with rising $C_{T}$, the ionic strength increases; consequently, the activity corrections are large and cannot be ignored; and (ii) numerical models consider the formation of aquatic complexes such as $\mathrm{NaHCO}_{3}^{-}$and $\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})$, which are absent in the analytical approach. The aquatic complexes become particularly relevant at high concentrations for $n=1$ and 2. [Note: At very high values of $C_{T}$ between 1 and $10 \mathrm{M} \mathrm{Na}_{2} \mathrm{CO}_{3}$ (i.e., the most upper part of the green curve), we exit the applicability range of common activation models.]

8.1 Strong Polyprotic Acids ..... 77
8.2 Mixtures of Acids ..... 79
$8.3 \quad \mathrm{H}_{\mathrm{N}} \mathrm{A}$ as Superposition of $N$ Monoprotic Acids ..... 79

### 8.1 Strong Polyprotic Acids

The math description of strong polyprotic acids is simpler than that of weak polyprotic acids, since strong acids never occur in the undissociated state at $\mathrm{pH} \gtrsim 0$ (at least one $\mathrm{H}^{+}$is always released). ${ }^{1}$

Because the amount of the undissociated species is zero, $[0]=0$ or $a_{0}=0$, it is not necessary to explicitly calculate the first dissociation step. In other words, we can remove (5.21) or (5.27) from our set of $N+3$ equations and completely forego the first dissociation constant $K_{1}$ (keeping in mind that $K_{1}$ is a large number - as discussed in $\S 2.1 .4)$. That is good news, because the first dissociation constant of strong acids is often not known precisely enough.

To simplify our analytical formulas, we use the fact that $K_{1}$ is very large. But instead of handling $K_{1} \rightarrow \infty$, it is easier to use the reciprocal case:

$$
\begin{equation*}
\text { strong acid: } \quad \frac{x}{K_{1}} \rightarrow 0 \quad \text { for all practice relevant } x \text { (i.e. } x \leq 1 \text { ) } \tag{8.1}
\end{equation*}
$$

Thus, we divide our analytical formulas by $K_{1}$ and then set all terms containing $x / K_{1}$ to zero (this is demonstrated, for example, in Appendix B.2.2 for the ionization fractions). In this way, $K_{1}$ disappears from all equations:

[^15]\[

$$
\begin{aligned}
& \text { general case } \\
& K_{1}, K_{2}, \ldots K_{N} \Rightarrow K_{1}, K_{2}, \ldots K_{N}
\end{aligned}
$$
\]

The cumulative acidity constants $k_{j}$ in (3.60) are also redefined:

$$
\begin{array}{lll}
k_{1}=K_{1} & \Longrightarrow & k_{1}=1 \\
k_{2}=K_{1} K_{2} & \Longrightarrow & k_{2}=K_{2} \\
k_{3}=K_{1} K_{2} K_{3} & \Longrightarrow & k_{3}=K_{2} K_{3} \tag{8.4}
\end{array}
$$

and so on.

## Ionization Fractions

The ionization fractions $a_{j}$, originally defined in (3.58), simplify as follows:

$$
\begin{array}{lll}
\text { general case } & \text { strong acid } \\
a_{0}=\left(1+\frac{K_{1}}{x}+\frac{K_{1} K_{2}}{x^{2}}+\ldots\right)^{-1} & \Rightarrow a_{0}=0 \\
a_{1}=\left(\frac{x}{K_{1}}+1+\frac{K_{2}}{x}+\ldots\right)^{-1} & \Rightarrow a_{1}=\left(1+\frac{K_{2}}{x}+\frac{K_{2} K_{3}}{x^{2}}+\ldots\right)^{-1} \\
a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0} & \Rightarrow a_{j}=\left(\frac{k_{j}}{x^{j-1}}\right) a_{1} \text { for } j>1 \tag{8.7}
\end{array}
$$

For the derivation see Appendix B.2.2.

## Polynomials

For strong acids, the polynomial in (5.35) becomes one degree less in $x$ (Note that the summation now starts with $j=1$ ):

$$
\begin{equation*}
0=\sum_{j=1}^{N}\left\{x^{2}+(n-j) C_{T} x-K_{w}\right\} k_{j} x^{N-j} \tag{8.8}
\end{equation*}
$$

Example $N=1$
For a strong monoprotic acid, the sum in (8.8) runs only over one single term, namely $j=1$. With $k_{1}=1$, we get a quadratic equation:

$$
\begin{equation*}
0=x^{2}+(n-1) C_{T} x-K_{w} \tag{8.9}
\end{equation*}
$$

Note that this equation does not contain any acidity constant.
Example $N=2$
For a strong diprotic acid, the polynomial in (8.8) becomes a cubic equation:

$$
\begin{equation*}
0=x^{3}+\left\{(n-1) C_{T}+K_{2}\right\} x^{2}+\left\{(n-2) C_{T} K_{2}-K_{w}\right\} x-K_{2} K_{w} \tag{8.10}
\end{equation*}
$$

This equation can also be derived from (5.38) by applying the condition $x / K_{1}=0$ from (8.1).

### 8.2 Mixtures of Acids

Until now we considered acid-base systems with one polyprotic acid. It is not difficult to extend the approach to mixtures of several polyprotic acids:

$$
\operatorname{acid} \mathrm{a}+\operatorname{acid} \mathrm{b}+\operatorname{acid} \mathrm{c}+\ldots \quad \text { with amounts of } C_{a}, C_{b}, C_{c}, \ldots
$$

The total sum of all acids will be abbreviated by $C_{T}=C_{a}+C_{b}+C_{c}+\ldots$ The equivalent fraction $n=n(x)$, i.e. the titration curve, of the multi-acid system (plus a strong base of amount $C_{B}=n C_{T}$ ) is then described by:

$$
\begin{equation*}
n=\tilde{Y}_{1}(x)+\frac{w(x)}{C_{T}} \tag{8.11}
\end{equation*}
$$

It has the same structure as (5.32), except $Y_{1}$ is replaced by the generalized moment $\tilde{Y}_{1}$ as a superposition of the individual acid's $Y_{1}$ :

$$
\begin{equation*}
\tilde{Y}_{1}=n_{a} Y_{1}^{(a)}+n_{b} Y_{1}^{(b)}+n_{c} Y_{1}^{(c)}+\ldots \quad \text { with coefficients } n_{\alpha}=\frac{C_{\alpha}}{C_{T}} \tag{8.12}
\end{equation*}
$$

The generalized moments $\tilde{Y}_{L}$ (here for $L=1$ ) are built in the usual way from the ionization fractions (i.e. according to (3.77)):

$$
\begin{equation*}
Y_{L}^{(\alpha)} \equiv \sum_{j=0}^{N_{\alpha}} j^{L} a_{j}^{(\alpha)} \tag{8.13}
\end{equation*}
$$

Here the ionization fractions $a_{j}^{(\alpha)}$ are determined by the (cumulative) acidity constants $k_{j}^{(\alpha)}$ of the individual acids, according to (3.25). The sum runs from $j$ $=1$ to $N_{\alpha}$, which is the number of protons of acid $\alpha(=a, b, c)$.

## Example: $\mathbf{H}_{3} \mathrm{PO}_{4}+\mathbf{H}_{2} \mathrm{CO}_{3}$

Given is a mixture of two acids: phosphoric acid plus carbonic acid with equal amounts: $C_{\text {phos }}=C_{\text {carb }}=C_{T} / 2$. The first moment $\tilde{Y}_{1}$ of the two-acid system is displayed as the blue curve in the upper diagram of Fig 8.1. It is simply the sum of $Y_{1}^{(\text {phos })}$ and $Y_{1}^{(\text {carb })}$. This curve approaches the value 5 when $\mathrm{pH} \rightarrow 14$, which is the degree of the two-acid system: $N=3+2=5$.

The bottom diagram in Fig 8.1 displays the individual ionization fractions of the two acids. To recall: The blue curve $\left(Y_{1}\right)$ in the top diagram represents the "titration curve" in the high- $C_{T}$ limit.

## $8.3 \quad \mathrm{H}_{\mathrm{N}} \mathrm{A}$ as Superposition of $N$ Monoprotic Acids

Is it possible to generate the titration curve of an $N$-protic acid (defined by $K_{1}$, $K_{2}$ to $K_{N}$ ) by a superposition of "virtual" $N$ monoprotic acids having the acidity constants $K_{1}, K_{2}$ to $K_{N}$ ? Answer: This is only possible approximately (never exactly). The underlying math will be demonstrated for the diprotic acid $\mathrm{H}_{2} \mathrm{~A}$.

Figure 8.1: $Y_{1}$ and $a_{j}$ for a system composed of phosphoric and carbonic acid.

Since the general formula for the titration curve $n(x)$ is $n=Y_{1}+w / C_{T}$ (see (5.32)), it is sufficient to focus on $Y_{1}$ :

$$
\begin{equation*}
Y_{1}=a_{1}+2 a_{2}=\left(a_{1}+a_{2}\right)+a_{2} \tag{8.14}
\end{equation*}
$$

From (3.58) we then get:

$$
\begin{array}{ll}
a_{1}+a_{2}=\left(\frac{K_{1}}{x}+\frac{K_{1} K_{2}}{x^{2}}\right)\left(1+\frac{K_{1}}{x}+\frac{K_{1} K_{2}}{x^{2}}\right)^{-1} & =\frac{K_{1}^{(\mathrm{a})}}{x}\left(1+\frac{K_{1}^{(\mathrm{a})}}{x}\right)^{-1} \equiv a_{1}^{(\mathrm{a})} \\
a_{2}=\frac{K_{2}}{x}\left(\frac{x}{K_{1}}+1+\frac{K_{2}}{x}\right)^{-1} & =\frac{K_{1}^{(\mathrm{b})}}{x}\left(1+\frac{K_{1}^{(\mathrm{b})}}{x}\right)^{-1} \equiv a_{1}^{(\mathrm{b})} \tag{8.16}
\end{array}
$$

Here we have introduced new acidity constants $K_{1}^{(\mathrm{a})}$ and $K_{1}^{(\mathrm{b})}$, which are (almost) identical with the two acidity constants of $\mathrm{H}_{2} \mathrm{~A}$ :

$$
\begin{array}{lll}
K_{1}^{(\mathrm{a})}=K_{1}\left(1+\frac{K_{2}}{x}\right) & \xrightarrow[\mathrm{pH} \rightarrow 0]{K_{2} / x \ll 1} & K_{1}^{(\mathrm{a})} \simeq K_{1} \\
K_{1}^{(\mathrm{b})}=K_{2}\left(1+\frac{x}{K_{1}}\right) & \xrightarrow[\mathrm{pH} \rightarrow 14]{\substack{ \\
}} & K_{1}^{(\mathrm{b})} \simeq K_{2} \tag{8.18}
\end{array}
$$

In fact, $a_{1}^{(\mathrm{a})}$ and $a_{1}^{(\mathrm{b})}$ are just the ionization fractions of the two monoprotic acids that
define their first moments $Y_{1}^{(\mathrm{a})}=a_{1}^{(\mathrm{a})}$ and $Y_{1}^{(\mathrm{b})}=a_{1}^{(\mathrm{b})}$. This leads to the conclusion:

$$
\underbrace{Y_{1}=a_{1}+2 a_{2}}_{\text {diprotic acid }} \Longleftrightarrow \underbrace{Y_{1}=Y_{1}^{(\mathrm{a})}+Y_{1}^{(\mathrm{b})}}_{\text {superposition of } 2 \text { monoprotic acids }}
$$

which can be extended to any $N$-protic acid:

$$
\underbrace{Y_{1}=a_{1}+2 a_{2}+3 a_{3}+\ldots}_{N \text {-protic acid }} \Longleftrightarrow \underbrace{Y_{1}=Y_{1}^{(\mathrm{a})}+Y_{1}^{(\mathrm{b})}+Y_{1}^{(\mathrm{c})}+\ldots}_{\text {superposition of } N \text { monoprotic acids }}
$$

Note that this is only an approximation, as indicated by the arrows in Eqs. (8.17) and (8.18). The "quality" of this approximation will be demonstrated in the following two examples.

## Two Examples

Two examples are presented in Fig 8.2 where $Y_{1}$ of carbonic acid $\left(\mathrm{H}_{2} \mathrm{~A}\right)$ and phosphoric acid $\left(\mathrm{H}_{3} \mathrm{~A}\right)$ are generated from two and three "virtual" monoprotic acids:

$$
\begin{array}{ll}
\text { carbonic acid : } & Y_{1}=a_{1}^{(\mathrm{a})}+a_{1}^{(\mathrm{b})} \\
\text { phosphoric acid : } & Y_{1}=a_{1}^{(\mathrm{a})}+a_{1}^{(\mathrm{b})}+a_{1}^{(\mathrm{c})}
\end{array}
$$

The blue curves in the present diagram are de facto indistinguishable from the blue curves (showing $Y_{1}$ ) in Fig 5.8.

Figure 8.2: $Y_{1}$ of carbonic and phosphoric acids generated as superposition of two and three "virtual" monoprotic acids.

## A <br> Activity Models

## Contents

A. 1 Activity vs Concentration ..... 85
A. 2 Activity Corrections ..... 86

## A. 1 Activity vs Concentration

Ions in solution interact with each other and with $\mathrm{H}_{2} \mathrm{O}$ molecules. In this way, ions behave chemically like they are less concentrated than they actually are (or measured). This effective concentration, which is available for reactions, is called activity:

$$
\text { activity }=\text { effective concentration } \leq \text { real concentration }
$$

The concentration [ $j$ ] of the aqueous species $j$ is converted to the activity $\{j\}$ using the activity coefficient $\gamma_{j}$ :

$$
\begin{equation*}
\{j\}=\gamma_{j}[j] \tag{A.1}
\end{equation*}
$$

In the limit of infinitely dilute systems, the activity coefficient becomes 1 :

$$
\begin{equation*}
\text { ideal solution: } \quad \gamma_{j}=1 \quad \Longrightarrow \quad\{j\}=[j] \tag{A.2}
\end{equation*}
$$

Since $\gamma_{j}$ corrects for electrostatic shielding by other ions, $\gamma_{j}$ depends on the ionic strength:

$$
\begin{equation*}
I=\frac{1}{2} \sum_{j} z_{j}^{2}[j] \tag{A.3}
\end{equation*}
$$

The sum runs over all ions in the solution. Due to the square of charge $z_{j}$, multivalent ions contribute particularly strongly to the ionic strength.

## A. 2 Activity Corrections

## A.2.1 Four Activity Models

For the activity corrections $\gamma$ or $\lg \gamma$, several semi-empirical approaches are available (each with its own validity range dictated by the ionic strength):
model
Debye-Hückel (DH): $\lg \gamma_{j}=-A z_{j}^{2} \sqrt{I}$
Extended DH: $\quad \lg \gamma_{j}=-A z_{j}^{2}\left(\frac{\sqrt{I}}{1+B \alpha_{j} \sqrt{I}}\right) \quad I<0.1 \mathrm{M}$
Davies:
$\lg \gamma_{j}=-A z_{j}^{2}\left(\frac{\sqrt{I}}{1+\sqrt{I}}-0.3 I\right) \quad I \leq 0.5 \mathrm{M}$
Truesdell-Jones: $\quad \lg \gamma_{j}=-A z_{j}^{2}\left(\frac{\sqrt{I}}{1+B \alpha_{j}^{0} \sqrt{I}}\right)+b_{j} I \quad I<1 \mathrm{M}$

## validity range

$$
I<10^{-2.3} \mathrm{M}
$$

All quantities carrying the subscript $j$ are ion-specific parameters ( $\alpha_{j}, \alpha_{j}^{0}$, and $b_{j}$ ). On the other hand, the two prefactors $A$ and $B$ depend on the temperature $T$ and the dielectric constant $\varepsilon_{r}$ :

$$
\begin{array}{ll}
A=A_{0} \cdot\left(\varepsilon_{r} T\right)^{-3 / 2} & \text { with } A_{0}=1.824 \cdot 10^{6} \mathrm{~K}^{3 / 2} \mathrm{M}^{-1 / 2} \\
B=B_{0} \cdot\left(\varepsilon_{r} T\right)^{-1 / 2} & \text { with } B_{0}=50.28 \mathrm{~nm}^{-1} \mathrm{~K}^{1 / 2} \mathrm{M}^{-1 / 2} \tag{A.9}
\end{array}
$$

For water at $25^{\circ} \mathrm{C}(T=298.15 \mathrm{~K})$ and with $\varepsilon_{r}=78.54 \mathrm{C}^{2} /(\mathrm{J} \cdot \mathrm{m})$, we get

$$
\begin{align*}
& A=0.5089 \mathrm{M}^{-1 / 2}  \tag{A.10}\\
& B=3.286 \mathrm{~nm}^{-1} \mathrm{M}^{-1 / 2} \tag{A.11}
\end{align*}
$$

Please note the length unit in the last equation: $1 \mathrm{~nm}=10^{-9} \mathrm{~m}=10$ Ångström. The derivation of the prefactors $A$ and $B$ is given in $\S$ A.2.2.

## Alternative Definitions (Two Pitfalls)

The prefactors $A$ and $B$ depend on the units chosen (and other conventions). So be careful when comparing them with other prefactors given in the literature.

Example 1. If the activity corrections are expressed in terms of $\ln \gamma$ (instead of $\lg \gamma$ ), then $A$ should be multiplied by $\ln 10$ :

$$
\begin{equation*}
A \quad \Longrightarrow \quad A \cdot(\ln 10)=1.172 \mathrm{M}^{-1 / 2} \tag{A.12}
\end{equation*}
$$

Example 2. If $B$ in (A.11) is expressed using the (non-SI) unit $\AA$ Angström (instead in nm), then $B$ should be divided by 10 :

$$
\begin{equation*}
B \quad \Longrightarrow \quad B / 10=0.3286 \AA^{-1} \mathrm{M}^{-1 / 2} \tag{A.13}
\end{equation*}
$$

## A.2.2 The Prefactors $A$ and $B$

The calculation of the prefactors $A$ and $B$ in $\S A .2 .1$ is based on the following physical constants:

$$
\begin{align*}
& N_{A}=6.022 \cdot 10^{23} \mathrm{~mol}^{-1}  \tag{A.14}\\
& e=1.602 \cdot 10^{-19} \mathrm{C}  \tag{A.15}\\
& k_{B}=1.381 \cdot 10^{-23} \mathrm{~J} / \mathrm{K}  \tag{A.16}\\
& \varepsilon_{0}=8.854 \cdot 10^{-12} \mathrm{C}^{2} \mathrm{~J}^{-1} \mathrm{~m}^{-1}  \tag{A.17}\\
& \varepsilon_{r}=78.54 \quad \text { (for water) } \tag{A.18}
\end{align*}
$$

Prefactor $A$

$$
\begin{equation*}
A=\frac{\sqrt{2 \pi N_{A}}}{\ln 10}\left(\frac{e^{2}}{4 \pi k_{B} \varepsilon_{0} \varepsilon_{r} T}\right)^{3 / 2}=A_{0} \cdot\left(\varepsilon_{r} T\right)^{-3 / 2} \tag{A.19}
\end{equation*}
$$

with

$$
\begin{aligned}
A_{0} & =\frac{\sqrt{2 \pi N_{A}}}{\ln 10}\left(\frac{e^{2}}{4 \pi k_{B} \varepsilon_{0}}\right)^{3 / 2} \\
& =\frac{\sqrt{2 \pi 6.02 \cdot 10^{23} \mathrm{~mol}^{-1}}}{\ln 10} \cdot\left(\frac{2.57 \cdot 10^{-38} \mathrm{C}^{2}}{4 \pi 1.38 \cdot 10^{-23} \mathrm{~J} / \mathrm{K} 8.85 \cdot 10^{-12} \mathrm{C}^{2} /(\mathrm{J} \cdot \mathrm{~m})}\right)^{3 / 2} \\
& =8.45 \cdot 10^{11} \mathrm{~mol}^{-1 / 2} \cdot\left(1.67 \cdot 10^{-5} \mathrm{~m} \cdot \mathrm{~K}\right)^{3 / 2} \\
& =8.45 \cdot 10^{11} \mathrm{~mol}^{-1 / 2} \cdot 6.83 \cdot 10^{-8}(\mathrm{~m} \cdot \mathrm{~K})^{3 / 2} \\
& =5.77 \cdot 10^{4} \mathrm{~K}^{3 / 2}\left(\frac{\mathrm{~m}^{3}}{\mathrm{~mol}}\right)^{1 / 2} \\
& =5.77 \cdot 10^{4} \cdot 10^{3 / 2} \mathrm{~K}^{3 / 2} \mathrm{M}^{-1 / 2} \quad\left(\text { with } \mathrm{M}=\frac{\mathrm{mol}}{\mathrm{~L}}=\frac{\mathrm{mol}}{10^{-3} \mathrm{~m}^{3}}\right) \\
& =1.824 \cdot 10^{6} \mathrm{~K}^{3 / 2} \mathrm{M}^{-1 / 2} \quad
\end{aligned}
$$

For water at $25^{\circ} \mathrm{C}$ we have:

$$
\begin{equation*}
\varepsilon_{r} T=78.54 \cdot 238.15 \mathrm{~K}=2.34 \cdot 10^{4} \mathrm{~K} \tag{A.21}
\end{equation*}
$$

which yields

$$
\begin{equation*}
\left(\varepsilon_{r} T\right)^{-3 / 2}=2.79 \cdot 10^{-7} \mathrm{~K}^{-3 / 2} \tag{A.22}
\end{equation*}
$$

Taken together, we obtain the result shown in (A.10):

$$
\begin{equation*}
A=A_{0} \cdot\left(\varepsilon_{r} T\right)^{-3 / 2}=0.5089 \mathrm{M}^{-1 / 2} \tag{A.23}
\end{equation*}
$$

## Prefactor $B$

$$
\begin{equation*}
B=\sqrt{\frac{2 N_{A} e^{2}}{k_{B} \varepsilon_{0} \varepsilon_{r} T}}=B_{0} \cdot\left(\varepsilon_{r} T\right)^{-1 / 2} \tag{A.24}
\end{equation*}
$$

with

$$
\begin{align*}
B_{0} & =\sqrt{\frac{2 N_{A} e^{2}}{k_{B} \varepsilon_{0}}}  \tag{A.25}\\
& =\left(\frac{2 \cdot 6.02 \cdot 10^{23} \cdot 2.57 \cdot 10^{-38}}{1.38 \cdot 10^{-23} \cdot 8.85 \cdot 10^{-12}} \cdot \frac{\mathrm{~m} \cdot \mathrm{~K}}{\mathrm{~mol}}\right)^{1 / 2} \\
& =\left(2.53 \cdot 10^{20} \frac{\mathrm{~m} \cdot \mathrm{~K}}{\mathrm{~mol}}\right)^{1 / 2} \\
& =1.59 \cdot 10^{10} \frac{\mathrm{~m}^{1 / 2}}{\mathrm{~mol}^{1 / 2}} \cdot \mathrm{~K}^{1 / 2} \\
& =1.59 \cdot 10^{10} \frac{1}{\mathrm{~m}} 10^{3 / 2} \frac{\mathrm{~K}^{1 / 2}}{\mathrm{M}^{1 / 2}} \quad\left(\text { with } \mathrm{M}=\frac{\mathrm{mol}}{\mathrm{~L}}=\frac{\mathrm{mol}}{10^{-3} \mathrm{~m}^{3}}\right) \\
& =50.3 \mathrm{~nm}^{-1} \mathrm{~K}^{1 / 2} \mathrm{M}^{-1 / 2} \quad\left(\text { with } 1 \mathrm{~m}=10^{9} \mathrm{~nm}\right)
\end{align*}
$$

For water at $25^{\circ} \mathrm{C}$, using (A.21), we obtain:

$$
\begin{equation*}
\left(\varepsilon_{r} T\right)^{-1 / 2}=6.54 \cdot 10^{-3} \mathrm{~K}^{-1 / 2} \tag{A.26}
\end{equation*}
$$

Taken together, we obtain the result shown in (A.11):

$$
\begin{equation*}
B=B_{0} \cdot\left(\varepsilon_{r} T\right)^{-1 / 2}=3.286 \mathrm{~nm}^{-1} \mathrm{M}^{-1 / 2} \tag{A.27}
\end{equation*}
$$

## B. 1 Polynomials in $x$

## B.1.1 The Subsystem $\mathrm{H}_{\mathrm{N}} \mathrm{A}$

The ionization fractions $a_{j}$ of an $N$-protic acid are functions of $x(j=1$ to $N)$ :

$$
\begin{equation*}
a_{j}(x)=\left(\frac{k_{j}}{x^{j}}\right) a_{0} \quad \text { with } \quad a_{0}(x)=\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right)^{-1} \tag{B.1}
\end{equation*}
$$

The task is to solve it for $x$, that is, to find a formula that calculates $x$ for a given value of $a_{j}$. This will lead to a polynomial of degree $N$ in $x$. For this purpose, let's start with $a_{0}$ and transform it in the following way:

$$
\begin{align*}
& \left.\frac{1}{a_{0}}=\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\ldots\right)=\frac{1}{x_{N}}\left(x^{N}+k_{1} x^{N-1}+\cdots+k_{N}\right) \right\rvert\, \cdot x^{N} \\
& \frac{x^{N}}{a_{0}}=x^{N}+k_{1} x^{N-1}+\cdots+k_{N}=\sum_{j=0}^{N} k_{j} x^{N-j} \tag{B.2}
\end{align*}
$$

It yields a polynomial of order $N$ in $x$ (i.e. the highest power of $x$ is $N$ ):

$$
\begin{equation*}
0=c_{0} \cdot x^{N}+k_{1} x^{N-1}+\cdots+k_{N} \quad \text { and } \quad c_{0} \equiv-\left(\frac{1-a_{0}}{a_{0}}\right) \tag{B.3}
\end{equation*}
$$

The result can be generalized to any other $a_{j}$. To do this, insert $a_{0}=\left(x^{j} / k_{j}\right) a_{j}$ into the left-hand side of (B.2):

$$
\begin{equation*}
\left(\frac{k_{j}}{a_{j}}\right) x^{N-j}=\sum_{i=0}^{N} k_{i} x^{N-i} \tag{B.4}
\end{equation*}
$$

Again, the obtained polynomial is of degree $N$ :

$$
\begin{equation*}
0=c_{j} \cdot x^{N-j}+\sum_{i \neq j}^{N} k_{i} x^{N-i} \quad \text { and } \quad c_{j} \equiv-\left(\frac{1-a_{j}}{a_{j}}\right) k_{j} \tag{B.5}
\end{equation*}
$$

For $j=0$ (and with $k_{0}=1$ ), this formula reduces to (B.3).

## B.1.2 The General Case: $\mathbf{H}_{\mathrm{N}} \mathbf{A}+\mathrm{H}_{2} \mathrm{O}+$ Strong Base

The titration of a polyprotic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$ by a strong base is described by (5.32), which we now write as

$$
\begin{equation*}
Y_{1}(x)=n-\frac{w(x)}{C_{T}} \quad \text { with } \quad n=\frac{C_{B}}{C_{T}} \tag{B.6}
\end{equation*}
$$

For $Y_{1}$ on the left-hand side, we apply (3.80). That is,

$$
\begin{equation*}
Y_{1}(x)=\frac{\sum_{j=0}^{N} j \cdot k_{j} x^{N-j}}{\sum_{j=0}^{N} k_{j} x^{N-j}} \tag{B.7}
\end{equation*}
$$

Inserting it into (B.6) and multiplying both sides by $\sum k_{j} x^{N-j}$ yields:

$$
\begin{aligned}
& \sum_{j=0}^{N} j \cdot k_{j} x^{N-j}=\left\{n-\frac{w}{C_{T}}\right\} \sum_{j=0}^{N} k_{j} x^{N-j} \\
& 0=\sum_{j=0}^{N}\left\{j-n+\frac{w}{C_{T}}\right\} k_{j} x^{N-j} \\
&=\sum_{j=0}^{N}\left\{C_{T}(j-n)+w\right\} k_{j} x^{N-j} \quad\left(\text { both sides are multiplied by } C_{T}\right) \\
&=\sum_{j=0}^{N}\left\{C_{T}(j-n)-x+\frac{K_{w}}{x}\right\} k_{j} x^{N-j} \quad(w \text { is replaced by }(5.34))
\end{aligned}
$$

After multiplication of both sides by $-x$, we get a polynomial of degree $N+2$ in $x$ :

$$
\begin{equation*}
0=\sum_{j=0}^{N}\left\{x^{2}+(n-j) C_{T} x-K_{w}\right\} k_{j} x^{N-j} \tag{B.8}
\end{equation*}
$$

To show that the polynomial is indeed of degree $N+2$ you can rewrite (B.8) as

$$
\begin{equation*}
0=\sum_{j=0}^{N+2} f_{j} x^{N+2-j} \quad \text { with } \quad f_{j}=k_{j}+k_{j-1}(n+1-j) C_{T}-K_{w} k_{j-2} \tag{B.9}
\end{equation*}
$$

The cumulative equilibrium constants $k_{j}$ are defined in (3.14). The first and the last coefficients of this polynomial are: $f_{0}=1$ and $f_{N+2}=-K_{w} K_{1} K_{2} \cdots K_{N}$. [Note: $k_{j}$ is per definition zero for negative values of $j$.]

Special Case: $C_{T} \rightarrow \infty$
Let us divide both sides of (B.8) by $C_{T}$ :

$$
\begin{equation*}
0=\sum_{j=0}^{N}\left\{\frac{x^{2}}{C_{T}}+(n-j) x-\frac{K_{w}}{C_{T}}\right\} k_{j} x^{N-j} \tag{B.10}
\end{equation*}
$$

In the limit $C_{T} \rightarrow \infty$, only the second term in the curly braces survives and thus (B.8) simplifies to a polynomial of degree $N+1$ :

$$
\begin{equation*}
0=\sum_{j=0}^{N}(n-j) k_{j} x^{N+1-j} \tag{B.11}
\end{equation*}
$$

## B. 2 Approximations for $a_{j}$

## B.2.1 Piecewise Linearization of $\lg a_{j}$

We start with the definition of $a_{0}$ in (3.58):

$$
\begin{equation*}
a_{0}^{-1}=\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}}\right)=\left(1+\frac{K_{1}}{x}+\frac{K_{1} K_{2}}{x^{2}}+\cdots+\frac{K_{1} K_{2} \cdots K_{N}}{x^{N}}\right) \tag{B.12}
\end{equation*}
$$

In each pH interval, as defined in the left diagrams in Fig 3.5 on page 29, we can approximate $a_{0}$ as follows (because $K_{1}>K_{2}>\ldots>K_{N}$ ):

$$
\begin{array}{lll}
0^{\text {th }} \text { interval }\left(\mathrm{pH}<\mathrm{pK}_{1}\right) & \text { where } x>K_{1} & \Longrightarrow a_{0}^{-1} \simeq 1 \\
1^{\text {st }} \text { interval }\left(\mathrm{pK}_{1}<\mathrm{pH}<\mathrm{pK}_{2}\right) & \text { where } K_{1}>x>K_{2} & \Longrightarrow a_{0}^{-1} \simeq k_{1} / x \\
2^{\text {nd }} \text { interval }\left(\mathrm{pK}_{2}<\mathrm{pH}<\mathrm{pK}_{3}\right) & \text { where } K_{2}>x>K_{3} & \Longrightarrow a_{0}^{-1} \simeq k_{2} / x^{2} \\
\cdots & & \\
\mathrm{~N}^{\text {th }} \text { interval }\left(\mathrm{pH}>\mathrm{pK}_{\mathrm{N}}\right) & \text { where } x<K_{N} & \Longrightarrow a_{0}^{-1} \simeq k_{N} / x^{N}
\end{array}
$$

Thus, we can approximate $\lg a_{0}$ in the $i^{\text {th }}$ interval by

$$
\begin{equation*}
\lg a_{0} \simeq \lg \frac{x^{i}}{k_{i}}=i \lg x-\lg k_{i}=-i \mathrm{pH}+\mathrm{pk}_{\mathrm{i}} \tag{B.13}
\end{equation*}
$$

where $\mathrm{pk}_{\mathrm{i}}=\mathrm{pK}_{1}+\mathrm{pK}_{2}+\cdots+\mathrm{pK}_{\mathrm{i}}$ and $\mathrm{pK}_{0}=0$.
The generalization of this result to all other $a_{j}$ is simple. Again, we refer to (3.58):

$$
\begin{equation*}
a_{j}=\left(\frac{k_{j}}{x^{j}}\right) a_{0} \quad \Longrightarrow \quad \lg a_{j}=\lg a_{0}+j \mathrm{pH}-\mathrm{pk}_{\mathrm{j}} \tag{B.14}
\end{equation*}
$$

Inserting the approximation (B.13) for $\lg a_{0}$ yields

$$
\begin{equation*}
\lg a_{j} \simeq(j-i) \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{\mathrm{j}}\right) \quad \text { for the } i^{\text {th }} \text { interval } \tag{B.15}
\end{equation*}
$$

This is a linear function of pH with integer-valued slope $(j-i)$ and offset $\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{\mathrm{j}}\right)$.

## Example: Phosphoric Acid

Phosphoric acid is defined by $N=3$ equilibrium constants ( $\mathrm{pK}_{1}=2.15, \mathrm{pK}_{2}=7.21$, $\mathrm{pK}_{3}=12.35$ ). Equation (B.15) is plotted in Fig 3.6 on page 30. Each $\lg a_{j}$ consists of four linear segments, with one segment in each interval $i$. In particular, we have:

- $a_{0} \simeq(0-i) \cdot \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{0}\right) \quad$ (blue dashed curve)

$$
\begin{array}{lll}
i=0: & (0-0) \mathrm{pH}+(0-0) & =0 \\
i=1: & (0-1) \mathrm{pH}+\left(\mathrm{pk}_{1}-0\right) & =-\mathrm{pH}+\mathrm{pK}_{1} \\
i=2: & (0-2) \mathrm{pH}+\left(\mathrm{pk}_{2}-0\right) & =-2 \mathrm{pH}+\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}\right)
\end{array}
$$

- $a_{1} \simeq(1-i) \cdot \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{1}\right) \quad$ (brown dashed curve)

$$
\begin{array}{rlll}
i=0: & (1-0) \mathrm{pH}+\left(0-\mathrm{pk}_{1}\right) & =\mathrm{pH}-\mathrm{pK}_{1} & \\
i=1: & (1-1) \mathrm{pH}+\left(\mathrm{pk}_{1}-\mathrm{pk}_{1}\right) & =0 & \\
i=0 & & =0 \\
i=2: & (1-2) \mathrm{pH}+\left(\mathrm{pk}_{2}-\mathrm{pk}_{1}\right) & =-\mathrm{pH}+\mathrm{pK}_{2} & \\
i=3: & (1-3) \mathrm{pH}+\left(\mathrm{pk}_{3}-\mathrm{pk}_{1}\right) & =-2 \mathrm{pH}+\left(\mathrm{pK}_{2}+\mathrm{pK}_{3}\right) & =-2 \mathrm{pH}+19.21 \\
i=35
\end{array}
$$

- $a_{2} \simeq(2-i) \cdot \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{2}\right) \quad$ (green dashed curve)

$$
\begin{aligned}
& i=0: \quad(2-0) \mathrm{pH}+\left(0-\mathrm{pk}_{2}\right)=2 \mathrm{pH}-\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}\right)=2 \mathrm{pH}-9.35 \\
& i=1:(2-1) \mathrm{pH}+\left(\mathrm{pk}_{1}-\mathrm{pk}_{2}\right)=\mathrm{pH}-\mathrm{pK}_{2} \quad=\mathrm{pH}-7.21 \\
& i=2:(2-2) \mathrm{pH}+\left(\mathrm{pk}_{2}-\mathrm{pk}_{2}\right)=0 \quad=0 \\
& i=3:(2-3) \mathrm{pH}+\left(\mathrm{pk}_{3}-\mathrm{pk}_{2}\right)=-\mathrm{pH}+\mathrm{pK}_{3} \quad=-\mathrm{pH}+12.35
\end{aligned}
$$

- $a_{3} \simeq(3-i) \cdot \mathrm{pH}+\left(\mathrm{pk}_{\mathrm{i}}-\mathrm{pk}_{3}\right) \quad$ (orange dashed curve)

$$
\begin{aligned}
& i=0:(3-0) \mathrm{pH}+\left(0-\mathrm{pk}_{3}\right)=3 \mathrm{pH}-\left(\mathrm{pK}_{1}+\mathrm{pK}_{2}+\mathrm{pK}_{3}\right)=3 \mathrm{pH}-21.7 \\
& i=1:(3-1) \mathrm{pH}+\left(\mathrm{pk}_{1}-\mathrm{pk}_{3}\right)=2 \mathrm{pH}-\left(\mathrm{pK}_{2}+\mathrm{pK}_{3}\right) \quad=2 \mathrm{pH}-19.55 \\
& i=2:(3-2) \mathrm{pH}+\left(\mathrm{pk}_{2}-\mathrm{pk}_{3}\right)=\mathrm{pH}-\mathrm{pK}_{3} \quad=\mathrm{pH}-12.35 \\
& i=3:(3-3) \mathrm{pH}+\left(\mathrm{pk}_{3}-\mathrm{pk}_{3}\right)=0 \quad=0
\end{aligned}
$$

## B.2.2 Strong Polyprotic Acids

The ionization fractions $a_{j}$ are defined in (3.58). They simplify for strong acids, where the condition $x / K_{1} \rightarrow 0$ holds for all relevant $x$ (as indicated in (8.1)).

Let's start with

$$
\begin{aligned}
a_{0}^{-1} & =\left(1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\ldots\right)=\frac{K_{1}}{x}\left(\frac{x}{K_{1}}+1+\frac{K_{2}}{x^{2}}+\ldots\right) \\
& =\frac{K_{1}}{x}\left(1+\frac{K_{2}}{x^{2}}+\ldots\right) \quad \text { because } x / K_{1} \simeq 0
\end{aligned}
$$

It yields

$$
\begin{equation*}
a_{0}=\frac{x}{K_{1}}\left(1+\frac{K_{2}}{x^{2}}+\ldots\right)^{-1}=0 \quad \text { because } x / K_{1} \simeq 0 \tag{B.16}
\end{equation*}
$$

According to the general formula $a_{1}=\left(K_{1} / x\right) a_{0}$, the term in the brackets in (B.16) represents $a_{1}$ :

$$
\begin{equation*}
a_{1}=\left(1+\frac{K_{2}}{x^{2}}+\ldots\right)^{-1} \tag{B.17}
\end{equation*}
$$

and we successively get

$$
\begin{align*}
& a_{0}=0  \tag{B.18}\\
& a_{1}=\left(1+\frac{K_{2}}{x^{2}}+\frac{K_{2} K_{3}}{x^{3}}+\ldots\right)^{-1}=\left(1+\frac{\tilde{k}_{2}}{x^{2}}+\frac{\tilde{k}_{3}}{x^{3}}+\ldots\right)^{-1}  \tag{B.19}\\
& a_{j}=\left(\frac{\tilde{k}_{j}}{x^{j-1}}\right) a_{1} \quad \text { for } j>0 \tag{B.20}
\end{align*}
$$

with "redefined" cumulative acidity constants $\tilde{k}_{j}$ :

$$
\begin{equation*}
\tilde{k}_{0}=0, \quad \tilde{k}_{1}=1, \quad \tilde{k}_{2}=K_{2}, \quad \ldots \quad \tilde{k}_{N}=K_{2} K_{3} \cdots K_{N} \tag{B.21}
\end{equation*}
$$

In this way, $K_{1}$ disappeared from all equations.

## B. 3 Simple Relationships between $a_{j}$ and $Y_{L}$

## B.3.1 Relationships for $Y_{L}$

The moments $Y_{L}$ are defined as finite sums over the ionization fractions $a_{j}$ :

$$
\begin{equation*}
Y_{L} \equiv \sum_{j=0}^{N} j^{L} a_{j}=0^{L} a_{0}+1^{L} a_{1}+2^{L} a_{2}+\cdots+N^{L} a_{N} \tag{B.22}
\end{equation*}
$$

with the special case $Y_{0}=1$ (mass balance) - see (3.63) and (3.78). [Note: $0^{0}=1$.]
An alternative relationship between $a_{j}$ and $Y_{1}$ can be established in the following sequence of steps:

$$
\begin{array}{ll}
n=n & \\
n Y_{0}=n & \text { (because } \left.Y_{0}=1\right) \\
n Y_{0}-Y_{1}=n-Y_{1} & \left(Y_{1}\right. \text { subtracted from both sides) } \\
n \sum a_{j}-\sum j a_{j}=n-Y_{1} & \text { (using (B.22) on the left-hand side) }
\end{array}
$$

which finally yields the result:

$$
\begin{equation*}
\sum_{j=0}^{N}(n-j) a_{j}=n-Y_{1} \quad \text { or } \quad \sum_{j=0}^{N}(n-j)[j]=\left(n-Y_{1}\right) C_{T} \tag{B.23}
\end{equation*}
$$

## Equivalence Points

The two types of equivalence points are characterized by (c.f. (3.69) and (3.70)):

$$
\begin{array}{llll}
\text { semi- } \mathrm{EP}_{\mathrm{j}}: & \mathrm{pH}=\mathrm{pK}_{\mathrm{j}} & \Longrightarrow & a_{j}=a_{j-1} \simeq \frac{1}{2} \\
\mathrm{EP}_{\mathrm{j}}: & \mathrm{pH}_{\mathrm{j}} \equiv \frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right) & \Longrightarrow & a_{j}\left(\mathrm{pH}_{\mathrm{j}}\right) \simeq 1 \tag{B.25}
\end{array}
$$

while all other ionization fractions are almost zero. In this way, the whole sum in (B.22) is reduced to one or two terms:

$$
\begin{array}{ll}
Y_{L}\left(\mathrm{pK}_{\mathrm{j}}\right)=(j-1)^{L} a_{j-1}+j^{L} a_{j}=\frac{1}{2}\left\{(j-1)^{L}+j^{L}\right\} & \text { for } L \geq 1 \\
Y_{L}\left(\mathrm{pH}_{\mathrm{j}}\right)=j^{L} a_{j} \simeq j^{L} & \text { for } L \geq 1 \tag{B.27}
\end{array}
$$

## B.3.2 Maximum of $a_{j}$

The maximum (extremum) of an ionization fraction $a_{j}$ is obtained under the condition that its $1^{\text {st }}$ derivative should vanish:

$$
\begin{equation*}
\frac{\mathrm{d} a_{j}}{\mathrm{dpH}}=0 \quad \Longleftrightarrow \quad \text { extremum of } a_{j} \tag{B.28}
\end{equation*}
$$

According to (B.47) on page 96, this is equivalent to the condition:

$$
\begin{equation*}
\left(j-Y_{1}\right) a_{j}=0 \quad \text { or } \quad j-Y_{1}=0 \tag{B.29}
\end{equation*}
$$

From (B.23) we get

$$
\begin{equation*}
\sum_{j=0}^{N}(j-i) a_{i}=0 \tag{B.30}
\end{equation*}
$$

or, more explicitly,

$$
\begin{equation*}
-j a_{0}-(j-1) a_{1}-\cdots-a_{j-1}+0+a_{j+1}+\cdots+(N-j) a_{N}=0 \tag{B.31}
\end{equation*}
$$

From the viewpoint of $a_{j}$, only its two neighbors $a_{j-1}$ and $a_{j+1}$ are of relevance (all other are nearly zero). Thus, (B.30) collapses to $-a_{j-1}+a_{j+1}=0$, that is

$$
\begin{equation*}
\operatorname{maximum~of~} a_{j} \quad \Longleftrightarrow \quad a_{j-1}=a_{j+1} \quad \text { or } \quad \frac{a_{j+1}}{a_{j-1}}=1 \tag{B.32}
\end{equation*}
$$

The pH at the maximum is obtained from (3.19):

$$
\begin{equation*}
\frac{a_{j+1}}{a_{j-1}}=\frac{[j+1]}{[j-1]}=\frac{K_{j} K_{j+1}}{x^{2}} \quad \Longrightarrow \quad x_{\max }=\left(K_{j} K_{j+1}\right)^{1 / 2} \tag{B.33}
\end{equation*}
$$

According to (3.45), the ionization fraction $a_{j}$ has its maximum at the equivalence point:

$$
\begin{equation*}
\text { maximum of } a_{j} \text { at } \mathrm{EP}_{\mathrm{j}} \quad \text { with } \mathrm{pH}=\frac{1}{2}\left(\mathrm{pK}_{\mathrm{j}}+\mathrm{pK}_{\mathrm{j}+1}\right) \tag{B.34}
\end{equation*}
$$

From mass conservation, i.e. (3.63), one gets the value of $a_{j}$ at the maximum as:

$$
\begin{equation*}
a_{j}\left(x_{\max }\right)=1-a_{j-1}-a_{j+1}=1-2 a_{j-1} \tag{B.35}
\end{equation*}
$$

which, in most cases, is close to 1 .

## B. 4 Derivatives with Respect to pH

## B.4.1 Basic Equations

Given is

$$
\begin{equation*}
x=\left\{\mathrm{H}^{+}\right\}=10^{-\mathrm{pH}}=e^{-(\ln 10) \mathrm{pH}} \tag{B.36}
\end{equation*}
$$

The $1^{\text {st }}$ and the $k^{\text {th }}$ derivative of $x$ with respect to pH are:

$$
\begin{align*}
\frac{\mathrm{d} x}{\mathrm{dpH}} & =-(\ln 10) x  \tag{B.37}\\
\frac{\mathrm{~d}^{k} x}{\mathrm{dpH}^{k}} & =-(\ln 10)^{k} x \tag{B.38}
\end{align*}
$$

This result is used to differentiate any given function $f(x)$ with respect to pH (by application of the chain rule):

$$
\begin{equation*}
\frac{\mathrm{d} f(x)}{\mathrm{d} \mathrm{pH}}=\frac{\mathrm{d} x}{\mathrm{~d} \mathrm{pH}} \frac{\mathrm{~d} f(x)}{\mathrm{d} x}=-(\ln 10)^{k} x \frac{\mathrm{~d} f(x)}{\mathrm{d} x} \tag{B.39}
\end{equation*}
$$

## Example 1

For $w(x)=K_{w} / x-x$, introduced in (4.7), we get:

$$
\left.\begin{array}{ll}
\frac{\mathrm{d} w(x)}{\mathrm{dpH}}=\ln 10\left(K_{w} / x+x\right) & =(\ln 10)(w+2 x) \\
\frac{\mathrm{d}^{2} w(x)}{\mathrm{dpH}^{2}} & =(\ln 10)^{2}(w+2 x-2 x) \tag{B.41}
\end{array}=(\ln 10)^{2} w\right)
$$

All higher derivatives repeat this pattern:

$$
\frac{\mathrm{d}^{k} w(x)}{\mathrm{dpH}^{k}}=(\ln 10)^{k} \begin{cases}w & \text { for } k \text { even }  \tag{B.42}\\ w+2 x & \text { for } k \text { odd }\end{cases}
$$

## Example 2

Let us consider the function, $g=1 / a_{0}$, that is

$$
\begin{equation*}
g(x)=1+\frac{k_{1}}{x}+\frac{k_{2}}{x^{2}}+\cdots+\frac{k_{N}}{x^{N}} \tag{B.43}
\end{equation*}
$$

Its first derivative is then given by

$$
\begin{equation*}
\frac{\mathrm{d} g(x)}{\mathrm{dpH}}=\ln 10\left(\frac{k_{1}}{x}+2 \frac{k_{2}}{x^{2}}+\cdots+N \frac{k_{N}}{x^{N}}\right)=\frac{\ln 10}{a_{0}}\left(a_{1}+2 a_{2}+\cdots+N a_{N}\right) \tag{B.44}
\end{equation*}
$$

where on the right-hand side, (3.25) was applied. Using the definition of $Y_{1}$ in (3.79), it yields the interesting result:

$$
\begin{equation*}
\frac{\mathrm{d} g(x)}{\mathrm{dpH}}=\frac{\mathrm{d}}{\mathrm{dpH}} \frac{1}{a_{0}}=\ln 10 \frac{Y_{1}}{a_{0}} \tag{B.45}
\end{equation*}
$$

## B.4.2 First Derivative of $a_{j}$ and $Y_{L}$

## Ionization Fractions

Let us start with the $1 / \mathrm{st}$ / derivative of $a_{0}$ by applying the results of the last example (particularly (B.45)):

$$
\begin{equation*}
\frac{\mathrm{d} a_{0}(x)}{\mathrm{d} \mathrm{pH}}=\frac{\mathrm{d}}{\mathrm{dpH}} \frac{1}{g(x)}=-\frac{1}{g^{2}} \frac{\mathrm{~d} g(x)}{\mathrm{dpH}}=-a_{0}^{2}(\ln 10) \frac{Y_{1}}{a_{0}}=(-\ln 10) Y_{1} a_{0} \tag{B.46}
\end{equation*}
$$

In the same way, we get from $a_{j}=\left(k_{j} / x_{j}\right) a_{0}$ the general result for each ionization fraction $a_{j}$ :

$$
\begin{equation*}
\frac{\mathrm{d} a_{j}(x)}{\mathrm{dpH}}=(-\ln 10)\left(Y_{1}-j\right) a_{j} \tag{B.47}
\end{equation*}
$$

## Moments

Applying the above results to the sums over $a_{j}$ yields

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{dpH}} \sum_{j=0}^{N} a_{j} & =(-\ln 10) \sum_{j=0}^{N}\left(Y_{1}-j\right) a_{j}=(-\ln 10)\left(Y_{1}-Y_{1}\right)=0  \tag{B.48}\\
\frac{\mathrm{~d}}{\mathrm{dpH}} \sum_{j=0}^{N} j a_{j} & =(-\ln 10) \sum_{j=0}^{N} j\left(Y_{1}-j\right) a_{j}=(-\ln 10)\left(Y_{1}^{2}-Y_{2}\right) \tag{B.49}
\end{align*}
$$

The first relation, which gives zero, is obvious because it represents the derivation of a constant, namely $\mathrm{d} 1 / \mathrm{dpH})=0$. Equation $(\mathrm{B} .49)$ is just the $1^{\text {st }}$ derivative of $Y_{1}$ :

$$
\begin{equation*}
\frac{\mathrm{d} Y_{1}}{\mathrm{dpH}}=(-\ln 10)\left(Y_{1}^{2}-Y_{2}\right) \tag{B.50}
\end{equation*}
$$

In the same way, for all higher moments $Y_{L}$ we get:

$$
\begin{equation*}
\frac{\mathrm{d} Y_{L}}{\mathrm{~d} \mathrm{pH}}=(-\ln 10) \sum_{j=0}^{N} j^{L}\left(Y_{1}-j\right) a_{j}=(-\ln 10)\left(Y_{1} Y_{L}-Y_{L+1}\right) \tag{B.51}
\end{equation*}
$$

## B.4.3 Higher Derivatives of $a_{j}$ and $Y_{L}$

The $2^{\text {nd }}$ derivative of $a_{j}$ is given by

$$
\begin{align*}
\frac{\mathrm{d}^{2} a_{j}(x)}{\mathrm{d} \mathrm{pH}} & =(-\ln 10) \frac{\mathrm{d}}{\mathrm{dpH}}\left(Y_{1}-j\right) a_{j} \\
& =(-\ln 10)\left\{a_{j} \frac{\mathrm{~d} Y_{1}}{\mathrm{dpH}}+\left(Y_{1}-j\right) \frac{\mathrm{d} a_{j}}{\mathrm{dpH}}\right\} \quad \text { (use of (B.47) and (B.50)) } \\
& =(-\ln 10)^{2}\left\{\left(Y_{1}^{2}-Y_{2}\right)+\left(Y_{1}-j\right)^{2}\right\} a_{j} \tag{B.52}
\end{align*}
$$

The $2^{\text {nd }}$ derivative of $Y_{1}$ is given by

$$
\begin{align*}
\frac{\mathrm{d}^{2} Y_{1}}{\mathrm{dpH}} & =(-\ln 10) \frac{\mathrm{d}}{\mathrm{dpH}}\left(Y_{1}^{2}-Y_{2}\right) \\
& =(-\ln 10)\left\{2 Y_{1} \frac{\mathrm{~d} Y_{1}}{\mathrm{dpH}}-\frac{\mathrm{d} Y_{2}}{\mathrm{dpH}}\right\} \\
& =(-\ln 10)^{2}\left\{2 Y_{1}\left(Y_{1}^{2}-Y_{2}\right)-\left(Y_{1} Y_{2}-Y_{3}\right)\right\} \\
& =(-\ln 10)^{2}\left\{2 Y_{1}^{3}-3 Y_{1} Y_{2}+Y_{3}\right\} \tag{B.53}
\end{align*}
$$

The $3^{\text {rd }}$ derivative of $Y_{1}$ is:

$$
\begin{align*}
& \frac{\mathrm{d}^{3} Y_{1}}{\mathrm{dpH}}=(-\ln 10)^{2} \frac{\mathrm{~d}}{\mathrm{dpH}}\left(2 Y_{1}^{3}-3 Y_{1} Y_{2}+Y_{3}\right) \\
& =(-\ln 10)^{2}\left\{3\left(2 Y_{1}^{2}-Y_{2}\right) \frac{\mathrm{d} Y_{1}}{\mathrm{dpH}}-3 Y_{1} \frac{\mathrm{~d} Y_{2}}{\mathrm{dpH}}+\frac{\mathrm{d} Y_{3}}{\mathrm{dpH}}\right\} \\
& =(-\ln 10)^{3}\left\{3\left(2 Y_{1}^{2}-Y_{2}\right)\left(Y_{1}^{2}-Y_{2}\right)-Y_{1}\left(3 Y_{1} Y_{2}-4 Y_{3}\right)-Y_{4}\right\} \tag{B.54}
\end{align*}
$$

## C

## Proton Balance

## Contents

C. 1 Diprotic Acid ..... 99
C. 2 General Case: N-protic Acid ..... 101

## C. 1 Diprotic Acid

PRL. The proton balance is often used in acid-base theory. It is a balance between the species that have excess protons versus those that are deficient in protons (relative to a defined proton reference level - PRL):

$$
\begin{equation*}
T O T \mathrm{H}=\text { excess protons }- \text { deficient protons } \tag{C.1}
\end{equation*}
$$

Subsystem $\mathbf{H}_{\mathbf{2}} \mathbf{O}$. The simplest case is pure water with its three species $\mathrm{H}^{+}, \mathrm{OH}^{-}$, and $\mathrm{H}_{2} \mathrm{O}$. Choosing $\mathrm{H}_{2} \mathrm{O}$ as the reference level, the species $\mathrm{H}^{+}$is enriched in 1 proton (excess proton), while $\mathrm{OH}^{-}$is depleted in 1 proton (deficient proton):

$$
\begin{array}{lll}
\text { PRL } & \text { excess protons } & \text { deficient protons } \\
\mathrm{H}_{2} \mathrm{O} & {\left[\mathrm{H}^{+}\right]} & {\left[\mathrm{OH}^{-}\right]}
\end{array}
$$

The proton balance of the subsystem "pure water" is then expressed by:

$$
\begin{equation*}
\left.\operatorname{TOT} \mathrm{H}\right|_{w}=\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]=-w(x) \tag{C.3}
\end{equation*}
$$

where $w(x)$ was introduced in (4.7). Thus, for pure water we have TOT H $\left.\right|_{w}=0$.
Because water is ever-present in an acid-base system, $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$are always a part of the proton balance - see Eqs. (C.15) and (C.16) below.

Subsystem $\mathbf{H}_{\mathbf{2}} \mathbf{A}$. The diprotic acid $\mathrm{H}_{2} \mathrm{~A}$ has three distinct reference levels denoted by $n=0,1$, and 2 :

## PRL excess protons deficient protons $\left.T O T \mathrm{H}\right|_{n}$

$$
\begin{array}{lllll}
n=0 & \mathrm{H}_{2} \mathrm{~A} & 0 & {\left[\mathrm{HA}^{-}\right]+2\left[\mathrm{~A}^{-2}\right]} & -\left[\mathrm{HA}^{-}\right]-2\left[\mathrm{~A}^{-2}\right] \\
n=1 & \mathrm{HA}^{-} & {\left[\mathrm{H}_{2} \mathrm{~A}\right]} & {\left[\mathrm{A}^{-2}\right]} & {\left[\mathrm{H}_{2} \mathrm{~A}\right]-\left[\mathrm{A}^{-2}\right]} \\
n=2 & \mathrm{~A}^{-2} & 2\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right] & 0 & 2\left[\mathrm{H}_{2} \mathrm{~A}\right]+\left[\mathrm{HA}^{-}\right]
\end{array}
$$

How to write down these equations?
In (C.4), $\mathrm{H}_{2} \mathrm{~A}$ is the reference level. There are no species that have more protons than $\mathrm{H}_{2} \mathrm{~A}$, hence, there is nothing to add to the left-hand side. Conversely, $\mathrm{HA}^{-}$is deficient by 1 proton and $\mathrm{A}^{-2}$ by 2 protons; therefore, both species enter the right-hand side. (If a species has lost 2 protons relative to the PRL, its concentration is multiplied by 2.)

In (C.5), HA ${ }^{-}$is the reference level. From this perspective, $\mathrm{H}_{2} \mathrm{~A}$ has 1 excess proton (the species enters the left-hand side), while $\mathrm{A}^{-2}$ is deficient by 1 proton (the species enters the right-hand side).

In (C.6), $\mathrm{A}^{-2}$ is the reference level. Now, $\mathrm{H}_{2} \mathrm{~A}$ has 2 excess protons and $\mathrm{HA}^{-}$ has 1 excess proton (both species enter the left-hand side); but there are no species that have less protons than $\mathrm{A}^{-2}$ (i.e. no species enters the right-hand side).

Taken together, the three PRL of the subsystem "diprotic acid", denoted by $\mathrm{H}_{2-\mathrm{n}} \mathrm{A}^{-\mathrm{n}}$ (for $n=0,1,2$ ), yield the following proton balance equation:

PRL TOTH $=$ excess protons - deficient protons

$$
\begin{equation*}
\left.\mathrm{H}_{2-\mathrm{n}} \mathrm{~A}^{-\mathrm{n}} \quad \operatorname{TOT} \mathrm{H}\right|_{n}=n\left[\mathrm{H}_{2} \mathrm{~A}\right]+(n-1)\left[\mathrm{HA}^{-}\right]+(n-2)\left[\mathrm{A}^{-2}\right]=0 \tag{C.7}
\end{equation*}
$$

This one-liner comprises all three equations (C.4) to (C.6). [Example: In the case of a carbonic-acid system the three PRL correspond to $\mathrm{H}_{2} \mathrm{CO}_{3}, \mathrm{HCO}_{3}^{-}$, and $\mathrm{CO}_{3}^{-2}$.]

Fig C. 1 illustrates how the choice of the origin (yellow dots) of a coordinate system ( $x$ axis: species; $y$ axis: number of excess/deficient protons) alters the proton balance equation.

For example, given a mono-, di-, and tri-protic acid we have for $n=0$ :

$$
\begin{array}{ll}
N=1: & \text { TOT }\left.\mathrm{H}\right|_{0}=-\left[\mathrm{A}^{-}\right] \\
N=2: & \text { TOT }\left.\mathrm{H}\right|_{0}=-\left[\mathrm{HA}^{-}\right]-2\left[\mathrm{~A}^{-2}\right] \\
N=3: & \text { TOT }\left.\mathrm{H}\right|_{0}=-\left[\mathrm{H}_{2} \mathrm{~A}^{-}\right]-2\left[\mathrm{HA}^{-2}\right]-3\left[\mathrm{~A}^{-3}\right] \tag{C.10}
\end{array}
$$

$\mathbf{H}_{\mathbf{2}} \mathrm{A}+\mathbf{H}_{\mathbf{2}} \mathrm{O}$. The combined system as the sum of subsystem "pure water" and subsystem "diprotic acid" obeys the proton balance for the three PRL at $\mathrm{H}_{2-\mathrm{n}} \mathrm{A}^{-\mathrm{n}}$ (with $n=0,1,2$ ):

$$
\begin{align*}
& \text { TOT }\left.\mathrm{H}\right|_{w}+\text { TOT }\left.\mathrm{H}\right|_{n}= \\
& \quad\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]+n\left[\mathrm{H}_{2} \mathrm{~A}\right]+(n-1)\left[\mathrm{HA}^{-}\right]+(n-2)\left[\mathrm{A}^{-2}\right] \tag{C.11}
\end{align*}
$$

The two species, $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$, that appear in this equation trace back to the $\mathrm{H}_{2} \mathrm{O}-$ reference level in (C.2). They have a permanent place in any $\mathrm{H}_{2} \mathrm{O}$ containing system.

Note: The PRLs are usually chosen at equivalence points $\mathrm{EP}_{n}$ (with integer $n)$. There is a direct correspondence between PRL at $n$ and $\mathrm{EP}_{n}$.

Figure C.1: PRL of a diprotic acid.

## C. 2 General Case: N-protic Acid

Subsystem $\mathbf{H}_{\mathbf{N}} \mathbf{A}$. It is not difficult to generalize the results of the previous paragraph to an $N$-protic acid $\mathrm{H}_{\mathrm{N}} \mathrm{A}$. It has $N+1$ distinct PRL (i.e. for each species $\mathrm{H}_{\mathrm{N}-\mathrm{n}} \mathrm{A}^{-\mathrm{n}}$ one proton reference level, or the corresponding $\mathrm{EP}_{n}$ ):

$$
\begin{array}{ll}
\text { PRL } \mathrm{H}_{\mathrm{N}-\mathrm{n}} \mathrm{~A}^{-\mathrm{n}}: \quad & \text { TOT }\left.\mathrm{H}\right|_{n} ^{\text {(acid })} \equiv n\left[\mathrm{H}_{\mathrm{N}} \mathrm{~A}\right]+(n-1)\left[\mathrm{H}_{\mathrm{n}-1} \mathrm{~A}^{-}\right]+ \\
& +(n-2)\left[\mathrm{H}_{\mathrm{n}-2} \mathrm{~A}^{-2}\right]+\ldots+(n-N)\left[\mathrm{H}_{\mathrm{n}-\mathrm{N}} \mathrm{~A}^{-\mathrm{N}}\right]=0 \tag{C.12}
\end{array}
$$

or in compact notation:

$$
\begin{equation*}
\operatorname{PRL} \mathrm{H}_{\mathrm{N}-\mathrm{n}} \mathrm{~A}^{-\mathrm{n}}: \quad \text { TOT }\left.\mathrm{H}\right|_{n} ^{(\text {acid })} \equiv \sum_{j=0}^{N}(n-j)[\mathrm{j}]=0 \tag{C.13}
\end{equation*}
$$

According to (B.23), the last equation can also be expressed by

$$
\begin{equation*}
\left.\operatorname{TOT} \mathrm{H}\right|_{n} ^{\text {(acid) }}=\left(n-Y_{1}\right) C_{T}=0 \tag{C.14}
\end{equation*}
$$

$\mathbf{H}_{\mathbf{N}} \mathbf{A}+\mathbf{H}_{\mathbf{2}} \mathbf{O}$. The proton balance of the whole system is the sum of (C.3) and (C.14):

$$
\begin{equation*}
\left.\left.T O T \mathrm{H}\right|_{n} \equiv T O T \mathrm{H}\right|_{w}+\left.T O T \mathrm{H}\right|_{n} ^{(\text {acid })} \tag{C.15}
\end{equation*}
$$

which is equivalent to

$$
\begin{equation*}
\left.\operatorname{TOT} \mathrm{H}\right|_{n}=-w+\left(n-Y_{1}\right) C_{T}=0 \tag{C.16}
\end{equation*}
$$

This proton-balance equation, in the form of $0=\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]+n C_{T}-Y_{1} C_{T}$, is equivalent to (5.25) and (5.31).

Charge Balance. The concept of proton balance is more general than the concept of charge balance (electro-neutrality). Only in the special case of $n=0$ do the charge balance and proton balance coincide:

The last equation is equivalent to the charge-balance equation:

$$
\begin{equation*}
0=\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}_{\mathrm{n}-1} \mathrm{~A}^{-}\right]-2\left[\mathrm{H}_{\mathrm{n}-2} \mathrm{~A}^{-2}\right]-\ldots-N\left[\mathrm{~A}^{-\mathrm{N}}\right] \tag{C.17}
\end{equation*}
$$

[^0]:    ${ }^{1}$ While acid-base reactions interchange electron-pairs, redox reactions are based on the exchange (of a sequence) of single electrons.

[^1]:    ${ }^{1}$ For example, an Arrhenius base can be abbreviated by BOH , where the cation $\mathrm{B}^{+}$stands for $\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{NH}_{4}^{+}$etc.

[^2]:    ${ }^{2}$ In organic acids, the second and third acidity constants can be similar.

[^3]:    ${ }^{3}$ The dissolved but undissociated neutral species is sometimes also abbreviated as $\mathrm{H}_{2} \mathrm{~A}^{0}$.

[^4]:    ${ }^{1} C_{T}$ becomes relevant only if, in addition to $\mathrm{H}_{\mathrm{N}} \mathrm{A}, \mathrm{H}_{2} \mathrm{O}$ and/or other acids and bases are present.

[^5]:    ${ }^{2}$ The index $j$ is always an integer; the index $n$ is both integer and half-integer.
    ${ }^{3}$ For simplicity we set here $x \simeq\left[\mathrm{H}^{+}\right]$, which deviates from our definition of $x$ as $\left\{\mathrm{H}^{+}\right\}$.

[^6]:    ${ }^{4}$ It was derived in § 3.1.4, see (3.29).

[^7]:    ${ }^{5}$ For a mathematician this isn't even as crazy as it seems (when acting on the complex RIEMANN sphere, for example).

[^8]:    ${ }^{6}$ Of course, it also provides an exact solution for monoprotic acids ( $N=1$ ), where $a_{0}$ and $a_{1}$ are given by (3.74) and (3.76).

[^9]:    ${ }^{7}$ To obtain the last equation you should multiply both nominator and denominator by $x^{N}$.

[^10]:    ${ }^{1}$ The derivation is presented in Appendix B.1.2 - see (B.8) for the special case $n=0$.

[^11]:    ${ }^{1}$ In [2], the equivalent fractions $n$ is abbreviated by $f$.

[^12]:    ${ }^{2}$ Here, the notation is extended to include the two external EPs by setting $[-1]=\left[\mathrm{H}^{+}\right]$and $[N+1]=\left[\mathrm{OH}^{-}\right]$.

[^13]:    ${ }^{3} \mathrm{Eq}$ (5.48) is more general than (5.43). Both equations are equivalent for $N \leq 2$, but deviate for higher $N$ (albeit the deviation is very small).

[^14]:    ${ }^{4}$ It is strictly valid for diprotic acids, but remains a very good approximation for $N$-protic acids with $N \geq 3$.

[^15]:    ${ }^{1}$ as shown in Fig 2.1 on page 11
